The most generally applicable of all, is undoubtedly the glass tube, which, for boilers in motion, such as locomotives, marine boilers, &c., is absolutely invaluable. Its mode of application deserves far more attention than it usually receives, the almost invariable practice being to fit it to the fire-box end of boilers, from the belief that there it will show exactly the amount of water over the fire-box, and because practically it is almost the only place where suitable space can be found for it; but as the water level is always very unsteady thereabouts, its indications are seldom very accurate, especially if the engine draws its steam from the same end of the boiler. In traction engines, in particular, we have seen the gauge fill and empty many times in a minute from the oscillation of the water, due to a rough road in a great measure. We would recommend the use of two tubes—one extending horizontally from the top of the glass nearly to the forward end of the boiler, where ebullition is least; the other in a similar way from the bottom of the glass. The end of this last should, of course, be suspended exactly at the minimum water level; and the tube should slope from the gauge the whole way, so that water may not lodge in it and cause a false indication.

Glass gauges are unhappily very liable to become stopped up, by the connections with the boilers getting filled with sediment; a remedy is not easily found, as any enlargement of the holes in the cocks and connecting-pipes might lead to very serious results should the glass tube burst. Some difficulty, too, is is found in getting tubes which will keep clear under a very heavy pressure; we have seen four tubes put in one after another in a locomotive working with 130 lb. steam in the course of an hour, although the same glasses answered admirably in a boiler working with 25 lb. steam; very high-pressure steam dissolves the glass, rendering it dim, soft, and brittle. Green glass tubes are far the best.

Some makers case their gauge in a slotted brass tube; we do not advocate the practice, none but an awkward fireman will break them by a blow, and they render the tube very difficult to keep clean, besides generally entailing some trouble in replacing or packing them.

For locomotives, marine and traction engines, we strongly recommend the use of two glass gauges; the second to replace the ordinary almost useless gauge-cocks. The first guage should be short, and fitted as we have already proposed; the second, fitted in the usual way, should be of very considerable length, say twenty to thirty inches, with a mark about the middle to show the exact top of the fire-box; in many cases the engineer may get his water short—quite out of the ordinary glass in fact—yet it may be very inconvenient, if not impossible, to stop and draw the fire, and he, depending on the fact that his gauge always so fitted as to just empty when there is still an inch or two of water on the top of his box, may go on until irreparable mischief is done. The second gauge would show exactly how far he might go in such a case with safety. On the other hand, by reaching to the top of the boiler it would show, if his ordinary glass were full to the top, exactly how much steam space he had left. The second glass, too, will prevent the necessity for the replacement of a burst glass until a convenient opportunity, and as both are very unlikely to get stopped up at the same time, will prevent such a mistake as a full glass with an empty boiler—a matter of very common occurrence. The additional expense will be very little, compared with the security and comfort of such an arrangement.

COMPOUND ENGINES.

The use of two cylinders, as a means of uniting the full economical advantages due to complete expansion, with the practical requirement of equable motion, seems to be attracting great attention amongst the engineers of the day. This was evinced in the Western Annexe of the Exhibition. In the engines shown by Mr.

Humphreys, similar to those working in the "Mooltan," the small cylinder was erected on the top of the large one, while the same piston-rod was used for both. Another marine-engine, sent from Sweden, had the small cylinder placed within the large one, and was made with three piston-rods, the high-pressure steam being admitted into the inner cylinder and allowed to expand in the outer. A 40-horse power horizontal compound engine was also exhibited by Messrs. Walter May and Co., of Birmingham. The two cylinders had their cranks at right angles, and the steam was expanded out of the small cylinder into the large one. A steam reservoir is required in this arrangement, as when at the end of the stroke of the small cylinder the crank of the large cylinder is at half stroke, and it is therefore so placed that the large cylinder cannot take steam. The steam reservoir was of wrought iron, and it was jacketted by high-pressure steam from the boiler. Mr. Wenham exhibited a very roughly got-up portable engine, also with two cylinders, and cranks working at right angles to each other. The exhaust steam was passed through a heated chamber, and was thus superheated on its passage from the smaller to the larger cylinder. The steam is thereby supplied with heat while expanding during the intermediate stage between the two cylinders. This seems a great step in advance of the use of merely a steam jacket for the reservoir.

Two valuable Papers were consecutively read last year before the Institution of Mechanical Engineers on Double Cylinder Expansive Engines. The first Paper was by Mr. William Pole, of London, favourably known to engineers by an esteemed work on the Cornish engine. Mr. Pole alluded to the use of two cylinders for pumping engines, and particularly in reference to the application of this arrangement to the engines erected by Messrs. Simpson at Lambeth Water Works, Thames Ditton. Mr. David Thomson, of London, in the second Paper, gave a full account of the construction and performance of these particular engines.

The double cylinder expansive steam engine is generally known under the name of "Woolf's engine," and this designation is more especially in vogue amongst Continental engineers. The first employment, however, of two steam cylinders, allowing the steam after it had acted in the first cylinder to be used a second time in the other, is undoubtedly due to Jonathan Hornblower. It is stated that the idea occurred to him in the year 1776; Hornblower patented his invention in 1781. In the specification he states:—"I employ the steam after it has acted in the first vessel to operate a second time in the other, by permitting it to expand itself, which I do by connecting the two vessels together." Hornblower thus *published* the invention some time before Watt; but the latter had previously applied the principle of expansion to single cylinder engines. Watt was, no doubt, aware that the full benefits of expansion could never be attained without the use of high pressures of steam; but he also knew that, in the then state of the mechanical arts, the employment of high pressures would be both difficult and dangerous. Besides, as regards the application of the double cylinder expansive engine for draining the Cornish mines, experience has proved that Watt was sound in his views in adopting the single cylinder. Both Hornblower and Woolf failed in generally introducing the double cylinder engine for the purposes to which pumping engines are generally applied in Cornwall. In any case, Hornblower's engine could not work well without using Watt's separate condenser; and Messrs. Boulton and Watt having gained an action at law against Hornblower for infringing their patent of 1769, the latter was reduced to poverty, and his double cylinder engine fell into abeyance. Having attempted to pirate another man's inventions, Hornblower was long denied what was really his own, and thus, at the revival of the double cylinder engine by Woolf in 1804, it went by the name of the latter engineer. Arthur Woolf, however, merely applied high-pressure steam to Hornblower's engine, and made it double-acting in order to obtain a rotary motion.

The above mainly refers to the use of the double cylinder engine in Cornwall, for pumping water; but a somewhat parallel case, on a smaller scale, is to be found in the history of the use of the double cylinder engine in the northern districts. This class of engine has been long technically known in Lancashire under the generic term of "compound engine;" an expression superior, in our opinion, and less liable to be misunderstood than that of "double cylinder engine." In 1800, Messrs. James and John Roberton, of Glasgow, patented a plan of using the steam on the same principle as that of Hornblower, but instead of placing the cylinders side by side, the high-pressure cylinder was placed at one end of the beam, and the low-pressure cylinder at the other end. In 1845, Mr. William McNaught, of Glasgow, patented the same thing for beam engines; but in order to adapt it to old engines already in use, the new high-pressure cylinder was, according to his plan, placed midway between the centre of the beam and the crank; the stroke of the high-pressure piston being thus half that of the condensing cylinder. What somewhat facilitated the introduction of this class of engine, was the want, often felt in the manufacturing districts, of increasing the mill power without much additional expenditure. An old engine, with an additional cylinder thus placed, is (or was) said, in Lancashire, to be "McNaughted." Several other patented plans have been brought forward at different times to relieve overloaded engines, without renewing the entire apparatus. One plan consists in applying an oscillating cylinder to the old crank shaft. Messrs. Musgrave, of Bolton-le-Moors, obtained a patent in 1855 for the application of a second condensing cylinder to an already existing beam engine. Both the cylinders are worked with one condenser and one air-pump.

Of course there is no theoretical gain in the use of two cylinders. The economical advantage of expansion is the same, whether developed in a single cylinder or a double cylinder engine. When, however, expansion is carried to any great extent in a single cylinder, there is a great irregularity of pressure at different parts of the stroke. The initial pressure at the beginning of every stroke produces violent concussions through the whole of the machinery, and in proportion to the degree of expansion used, the evil will increase. In the ordinary cases, where large pumping engines are used, uniformity of motion is not required; and, besides, with a single cylinder pumping engine, without a crank and fly-wheel, the initial blow is at once absorbed by the inertia of the mass. The ordinary Cornish engine is generally made with a single cylinder working a loaded plunger; because in simply raising water from a deep pit no great regularity of motion is required, the rods have plenty of time to come to rest, and the work is not subject to fluctuations. The case is, however, different when the water has to be pumped direct into a town or into a remote reservoir. The water is necessarily taken off from the mains at irregular intervals, producing considerable variation in the pressure. As Mr. Hawksley stated, in the discussion that ensued upon the two Papers we have alluded to, and in reference to engineering practice in water works: "It is found useful in these cases to apply a fly-wheel, and it was also desirable to carry out the expansion to a considerable extent, as the steam could in practice be expanded further when a fly-wheel was used than in the Cornish engine without a fly-wheel. It therefore became a consideration how best to get this increased amount of expansion; and the double cylinder engine was found to afford the means of so limiting the initial blow of the steam that practically there was no necessity for employing a great weight of material to obtain the requisite strength in the engine, since the strain on all the machinery could be reduced to a minimum for a given power, by properly adjusting the proportions of the two cylinders, and cutting off at the proper point of the stroke in the small cylinder."

In the larger classes of engines, with reciprocating parts of a necessarily heavy character, the advantage of using two cylinders makes itself peculiarly felt, as equability of motions is a *sine quâ non* for the permanent stability of such heavy machinery. Even with Cornish pumping engines, when high pressures of steam are used, there is a necessity for diminishing the risk of fracture from the initial blow of the entering steam, by the use of double cylinder engines. Mr. Sims, of Redruth, in Cornwall, first contrived the simple plan of double cylinder engine for this purpose, in which the small cylinder stands on the top of the larger one, and the same piston-rod is used for both cylinders. The number of valves is also the same as in the common pumping engine.

When it is wished to obtain a high degree of expansion in marine and other rotary engines, with a single cylinder, the amount is limited to an extent of three or four times, from the great strain at the commencement of the stroke, compared with the mean force of the entire stroke. In these engines the initial blow is not absorbed by the inertia of a large mass to be put in motion at the beginning of the stroke, forming a reservoir of power for the steam while expanding through the remainder of the travel of the piston. Compounded engines are, in this case, peculiarly advantageous, as is instanced by the success of the engines on this plan, built by Mr. Humphreys, for the "Mooltan" and other vessels. Of course steam-engine economy almost always involves additional weight and expense in the engine. This is, however, in this case, compensated by the reduced number of boilers and furnaces required in developing a given amount of power—a fact which is not seldom lost sight of when estimating the relative advantages of compounded and single-cylinder engines.

The pumping engines for the Lambeth Water Works Company, described in the Papers of Messrs. Pole and Thomson, required great equability of motion, and a complete avoidance of all concussions and irregularities of pressure, as the water had to be forced along a cast-iron main, nine miles long, and 30 in. diameter. From the large amount of steam power required, great economy of fuel was also necessary. For these reasons, the engines described in Mr. David Thomson's Paper were erected. They are beam engines, with double cylinders, with cranks and connecting rods. "Four engines of 150-horse power are fixed side by side, arranged in two pairs, each pair working on to one shaft, with cranks at right-angles, and a fly-wheel between them." The strokes of the crank and of the large cylinder are the same. The smaller cylinder has a shorter stroke, and its effective capacity is almost one-fourth of that of the large cylinder. The principal peculiarity in the engines consists in the steam being cut off in the *small* cylinder before the end of the stroke, and the expansion is then allowed to proceed from that point, and according to an analytical investigation given by Mr. Pole in an appendix to his Paper, the most advantageous point of the stroke for cutting off varies in the small cylinder with the extent of expansion adopted in the engine.

The main objection to the compound engine consists in its additional complication and weight. This is, however, as we remarked above, generally compensated by a reduction in the number of boilers and furnaces required. The plan of compounding engines has been often very injudiciously carried out in Lancashire; and arrangements have been adopted evincing disgraceful ignorance of the requirements of the case. As Mr. Pole stated, "There is a peculiarity in the double cylinder engine in its requiring a pipe or passage of some kind through which the steam must travel from one end of the small cylinder to the opposite end of the large one; and this passage should evidently be as small in content as possible, consistently with allowing the free passage of the steam. When the communication is opened at the end of the stroke, the steam passing from the small cylinder has to expand and fill this passage before it enters the large cylinder; and, if the passage be large, the steam must necessarily suffer a reduction of pressure in so doing, which must seriously diminish its effective action on the large piston during the future stroke, and so cause much loss." In some engines Mr. Pole found this loss so great as to waste nearly half the power of the engine; and, even in the best that were examined, such a considerable percentage of loss occurred as almost to neutralize the benefit of expansion altogether. Mr. Scott Russell, in the discussion that followed the reading of the Papers, stated that, in order to get over the difficulty of repairs, arising from the complexity of the double cylinder engine, he had arranged an engine with three independent cylinders; and each cylinder expanded the steam about four times, and they all worked direct on one crank. Mr. Scott Russell said that the consumption of coal with this engine was as low as 2½ lb., and even 2 lb., per horse power per hour. This arrangement, of course, increases the number of the parts; but, at the same time, they are all easy of access, and the engine, as a whole, could not be easily disabled for work.

Every arrangement in engineering, like almost every course in life, has its own peculiar merits and demerits; and each special problem has its own peculiar difficulties and facilities. The art of the expert engineer is shown in his skilful adaptation of any special arrangement with its attendant advantages and disadvantages to the peculiar exigencies of any given case.

COLLIERY LOCOMOTIVES.

Not the least item of expense connected with the working of a coal, or indeed any other mine, is the conveyance of its produce to the place where it becomes useful. The sinking of shafts, the erection of pumping and winding machinery, nay, the very raising of the coal, or ore, to the surface—operations attended as they are with risk and expense in no slight degree—are, after all, in most cases, but preliminary operations, which require the addition of a means of transit, safe, expeditious, and economical, before the miner can hope to reap any return for his labour, capital, and skill. The railway station or the wharf is usually at a considerable distance from the pit's mouth. Blast furnaces, although at first erected as close as possible to the mine, in the course of a few years, or even months, exhaust the veins in their immediate neighbourhood, rendering the sinking of new shafts at greater distances a matter of necessity, hence the transfer of materials to supply them becomes a matter of serious importance to their proprietors.

In the mining districts generally we see lines of railway, or tramway rather, laid down from the pit's mouth to the wharf, the railway station, or the blast furnace, on which waggons capable of holding from a ton and a half to three tons, or even more, are drawn in trains of two or more by teams of horses. These railways are for the most part of the rudest construction. The sharpest curves and steepest inclines are considered matters of little importance; contractors' rails worn to the last, and, when new, of all patterns, spiked in the most negligent fashion to sleepers, which are seldom replaced so long as a rail can rest on, without actually going through them, from the permanent way. Scarcely an attempt is made to keep the joints good, or the rails of an equal height; when, in addition, we remember that the gauge seldom exceeds 2 ft. 6 in.—3 ft. being unusual, and 4 ft. seldom or never met with—we are very liable to draw the conclusion that a more unpromising road to work with locomotives cannot possibly be met with, even in the wilds of America.

On much such a road, nevertheless, did steam, in the hands of George Stephenson, commence that great era of locomotion which is the distinguishing characteristic of the 19th century; but, although railways spread in all directions around us, the modern engineer, discouraged by the unpromising field, has failed to introduce the locomotive to any great extent, as a substitute for horse labour, on such lines as George Stephenson had to deal with. Colliery proprietors and ironmasters, believing it impossible to work locomotives successfully under the circumstances, prefer to employ expensive horse-labour, contending, that any advantage to be derived from the employment of an engine, would not compensate for the large outlay necessary to improve their roads to such an extent as they believe requisite to ensure the working of a locomotive with success. In many cases, too, the purchase of land necessary to straighten a line, would entail an enormous expense; besides, rival proprietors' lines often cross one another, so that raising one might cause such an incline on another as to render it useless; all these things considered, we see apparently good reason why horse labour is still adhered to.

Now, we believe that the conclusions which have led to this result, have been arrived at too hastily, and without sufficient reflection—without, in short, a sufficiently careful examination into what the qualifications of the locomotive for such situations actually are. An acquaintance with it only when drawing heavy passenger trains, at a lightning speed on a line so perfect that the first-class passenger may imagine himself passing over velvet, gives but little idea of the actual capabilities of suitable engines even on the worst roads, and under the most difficult circumstances. If carriages propelled by steam can proceed with ease, safety, and expedition, not only on common roads, but even down, aye, and up, our green English lands, how much more likely are they to succeed on a road into which at least they cannot sink? a road indeed, which, with all its imperfections, will permit a horse to draw at least twice as much as he can on the best turnpike. The construction of engines which will do good service in those cases, is not a problem which presents as many difficulties as we may imagine at a first glance. At a low speed, carriages, whether drawn by horses or propelled by steam, may proceed over even the worst track with comparative ease; and, we feel certain, that light locomotives with low wheels, and a very short wheel-base, may be worked with success on almost any of the lines now worked by horse-power. The loads to be drawn need, in no case, exceed 60 tons, or the pace 7 or 8 miles an hour—5 will usually be found quite fast enough for all ordinary requirements; and as the existing waggons, which will in most cases have to be returned in active service, seldom extend 20 in. in height from the rail to the side beams, no possible advantage can be gained by placing the engine on high wheels, which entail a great deal of trouble in the attempt to keep the buffer-beam low enough to suit the waggons. A low wheel, too, ensures a good blast in the chimney, by enabling the pistons to make a fair number of strokes in a minute. We believe that 2 ft. 6 in. will be found a good general diameter. As to material, nothing can be better than cast iron, with steel tyres. The rails are in general covered with so much dirt and grit, owing to their small elevation above the surface of the ground, that wrought iron suffers rapid wear. Steel tyres appear to deserve the high character they bear, for such purposes at least.

Too much care cannot be taken to make the bearing of such engines stiff, as outside cylinders must be adopted, and these, of considerable diameter and at some distance from the frame, exert a powerful tendency to bend it; and, the imperfections of the road added to this, would quickly pull everything to pieces were not strong cross braces and plates introduced between the frames. For this reason, as well as another which we will refer to further on, the best practice would be to adopt some such arrangement as Forester used in his first engines—that is, to place the valve chests outside of the frame on top of the cylinders, working the valves by means of a suitable rocking shaft. Although the engines first constructed on this principle gained the name of "Boxers," from their oscillation at high speeds, no objection can apply to them when running at speeds under ten miles an hour; and it was not the arrangement of the valve chests, but of the cranks, whch caused them to fall into disfavour with engineers. When we remember that the space between the frames of an engine for a 2 ft. 6in. gauge is but 20 in., when the frame is, as it should be, inside the wheels, we at once see the great advantage gained by the adoption of any arrangement which leaves that space in occupied machinery, and permits the introduction of strong plates between the frame to impart the necessary stiffness.

As the wheel-base is generally very limited, owing to the unusually sharp curves generally met with on colliery railroads, the distribution of weight becomes a very important consideration. As but four wheels are admissible, and they of course coupled, means must be adopted to secure sufficient weight on the leading pair for the purposes of adhesion, as well as the preservation of the permanent way, which, being weak, is quickly destroyed by overloading a single pair of wheels. This same distribution of weight is a very troublesome problem, from the fact that the fire-box being wider than the gauge of the line by many inches cannot go between the wheels, and, united to the weight of the foot plate, which must be of some size, to carry coals, far overbalancing the cylinder end of the engine; the light smoke-box proving no match for the heavy fire-box. We have seen it necessary to resort to a cast-iron buffer-beam in front, ere now, to get over the difficulty.

A proper disposition of the centre of gravity may always be secured by placing the water tank between the frames under the front end of the engine, and fixing a large steam dome on the top of the boiler, as close as possible to the chimney. Where a wheel-base of 5 ft. or 6 ft. can be secured, this will invariably give a steady engine, although it may overhang the wheels as much as 5 ft. or 6 ft. at each end; and, in order to obtain space for a water tank in the situation named, it is evident that all the working machinery must be outside, with the exception of the link motion and eccentrics. Another advantage in placing the valve chest outside will be found in the ease with which steam-tight joints may be made and broken when easy of access, which they cannot be within the smoke-box or under an engine at once so low and narrow. The constant jolting, too, to which the engine is exposed is very apt to break the steam-pipe joints, unless some elastic arrangement is adopted.

Ample cylinder room should be provided, to meet the exigencies of an undulating road; it is of little consequence if the boiler is unable to furnish full pressure steam to the cylinder for long periods together; they will seldom exert a constant drain on the boiler, and, besides securing economy (not, indeed, that that is of much importance in a coal district) by working in general on a high grade of expansion, will, with 100 lb. steam, give ample power for any possible exertion the engine may be called on to make in ascending a steep part of the road, &c. We know many lines, which in general tolerably level, have one or two inclines of perhaps 1 in 30 or 1 in 40, a hundred yards long, or so. Over such inclines the train, from its slow speed, possesses no impetus to aid the engine—as the drivers say, "It is all dead pull." Large cylinders prevent any difficulty in such cases.

Where machinery is already so much cramped for room, it is almost needless to say that a pump is inapplicable. A No. 5 Giffard Injector is superior in every respect; room is easily found for it on the foot-plate.

Horses cannot compete in economy with light locomotives such as we speak of. The cost of fuel is almost nominal; and although we do not for a moment advocate bad roads, still we do not hesitate to say that in few cases need we be deterred by their imperfect condition from employing a locomotive suitable to their requirements. Money will be expended to advantage in improving such lines; this being done by degrees, may often be effected almost insensibly; every such improvement will well repay the outlay, by adding to the durability of the engine and reducing wear and tear.

Everything which tends to cheapen produce confers a benefit on the consumer. The public generally are large consumers both of coal and iron, and we believe the introduction of light locomotives on colliery railroads a matter of some interest to the community at large.

A plan has been prepared by Mr. Thomson, of Glasgow, architect, for the extension of the line of Ingram-street, in that City, to the High-street front of the University.

NAVAL ARMOUR EXPERIMENTS AT SHOEBURYNESS.

[From our special Reporter.]

THE experiments on iron-clad targets in progress at Shoeburyness derive a special interest from the fact that their object is to test the value of systems of backing to armour plates which have not yet been tried. In the construction of our mailed ships of war, whether of iron or wood, the plates without any exception are backed with teak. The "Warrior" plan—4½ inch plates on 18 inches teak—has been the type, which, however, is modified in the "Minotaur" class, by increasing the thickness of the plates to 5½ inches, and reducing that of the teak to 10 inches. No iron-clad has been constructed or designed up to the present time with any other kind of backing to the armour but wood. Two years ago the Iron Plate Committee, as well as several shipbuilders, doubted the efficiency of wood as backing. The idea of incorporating the weight of the teak in the armour, or in the structure of the ship, prevailed, and the Admiralty had targets constructed on that principle on plans proposed by Mr. Fairbairn, Mr. Samuda, and Mr. Scott Russell. These were experimented upon, and proved less efficient than the "Warrior" system. But in all these cases, there was in fact no backing. The armour plates were bedded on a frame representing the hull of an iron ship.

A system of iron cells or girders, in lieu of wood, as backing to the armour plates, with perfect rigidity of fastening, has been for some time under consideration. Being recommended for trial by the committee, the Admiralty ordered a target on that plan to be constructed, and it will, when completed, be submitted to the usual tests at Shoeburyness. In the meantime, Mr. J. Chalmers, C.E., the projector of a submarine railway between Dover and Calais, of which the drawings were exhibited at the International Exhibition, in connection with Sir Morton Peto, M.P., who is a partner in the Millwall Shipbuilding Company (late Messrs. C. J. Mare and Co.), had a target constructed which partially adopts the iron cellular backing principle, but without rigidity. This is the target experimented upon on Monday last, under the direction of the Special Committee on Iron, and is thus described in their programme: "The target proposed by Mr. Chalmers to test his plan of armour plating, and constructed by the Millwall Iron Works (13 ft. 4 in. long, and 10 ft. high), is composed of three 3½-inch armour plates, backed by alternate layers of timber and iron; and then there is a second armour plate 1½ inch thick, with a cushion of timber between it and the skin of the ship, the fastening bolts have stepped conical necks and a square thread. The trial to consist of the following rounds—Nos. 1, 2, 3, 110-pounder rifled gun, 12 lb. charge, shell filled with sand 104 lb. weight. Nos. 4 and 5, 68-pounder smooth-bore gun, 16 lb. charge, shell filled with sand 40½ lb. weight. Nos. 6, 7, 8, 9, 10, live shell with the same guns and charges. Nos. 11, 12, 13, 110-pounder rifled gun, 14 lb. charge, solid 110 lb. cast-iron shot. No. 14, 68-pounder smooth-bore gun, 16 lb. charge, solid cast-iron shot 66½ lb. Nos. 15, 16, 17, 110-pounder rifled gun, 10 lb. charge, solid 200 lb. cast-iron shot. Nos. 18, 19, 20, three 200 lb. solid cast-iron shot in salvo. No. 21, 68-pounder, 16 lb. charge, solid cast-iron 66½ lb. shot. Nos. 22, 23, 24, 110-pounder rifled gun, 14 lb. charge, and Nos. 25, 26, 68-pounder smooth-bore, 16 lb. charge, to be fired in salvo with solid cast-iron shot. No. 27, 110-pounder rifled gun, 16 lb. charge, steel jacket shot, flat ended, 109 lb. weight. The above trial is similar to the first day's experiments on the original "Warrior" target, with the exception that no experimental guns are used in the present trial."

To understand the system of the target, some explanation is required.* The "layers of timber and iron" are teak planks 11 in. wide and 4½ in. thick, and iron plates of the same width ½ of an inch thick, laid horizontally, and alternately one upon another. They abut behind against the 1½ in. plate. Vertically they are held together by 1 in. iron rods, 10 ft. long, with screw ends and nuts, holes being drilled through these planks and plates for the passage of the iron rods. Some bolts are passed horizontally through some of the planks, and screw up inside the skin. But in this arrangement there is an obvious want of cohesion, which the inventor compensated by an abundant appliance of caulking, red lead and marine glue. The backing, as well as the armour plates, in fact, rely mainly upon the through bolt fastenings with "stepped conical necks" for adhesion to the structure they are intended to protect. The bolt heads are supported with heavy iron washers, fixed immediately at the back of the bolt holes of the armour plates. The main feature of the plan is the wooden cushion interposed between the backing and the skin of the ship. It is meant to act as a buffer, yielding to the blow, and tending to diminish recoil. This effect being realized would, however, counteract rigidity. The results will show how far the expectations formed have been realized.

In accordance with the programme and previous target trials, the experiments commenced with three 110-pounder, and two 68-pounder shells filled with sand, followed by the same number and description of live shells, each one fired singly. The object of this practice is to test the effect of vibration on the plates and structure generally, but especially on the fastenings. The indentations from the 110-pounder elongated rifled shells were from ½ to 1 in., and from the spherical 68-pounders about 1½ in. in depth. Two plates were driven in ½ to 1½ in. at the edges where the shells struck, and exhibited rather extensive cracks in various directions, running from the bolt holes—some concentric at the points of impact, some horizontal, and some angular. These cracks, which were more numerous than those on the "Warrior" section with the same shell practice, are, no doubt, to be attributed to the heavy iron washers, introduced at the back of the plates under the heads of the bolts, acting as bearing points at the bolt holes, so that instead of affording support, they become sources of weakness. The bolts themselves suffered no damage, not a nut or washer was in the least displaced; the ship's frame sustained no injury, except 10 or 12 small rivet heads chipped off. No. 11, a solid 110-pounder rifled shot struck the top plate at the left end, buckled it longitudinally 3 in., and made an indent 6·7 in. by 1·2 in., caused a deep crack across the indent, and separated the plate 3 in. from the backing at the top. Nos. 12 and 13, solid 110-pounders, produced nearly similar effects on the middle and bottom plates. No. 14, a solid 68-pounder, made an indentation 2¼ in. deep by 8½ in. at the right end of the middle plate, and slightly cracked it. Still, from these four solid shot, the bolts showed no sign of damage. Inside the skin, 7 or 8 more small rivet heads came off. No. 15, 16, 17, three 200 lb. shot with 10 lb. charge, fired singly, produced indents of less than an inch in depth, broke off two small backing bolt nuts, and cracked a plate slightly at the impact. Nos. 18, 19, 20, a salvo of 200 lb. solid shot, fired with 10 lb. charge from 110-pounder guns, at the centre of the middle plate, did no damage to the plate beyond a few slight cracks from bolt holes; but four of the frames were bowed inwards by the heavy weight of metal—two about 1½ in. from the perpendicular, and two slightly, but without any fracture. The armour bolts again remained unhurt, although one was struck on the head. These heavy projectiles, however, with small charges and at low velocities are usually not very damaging. No. 21 was a miss. Nos. 22, 23, 24, three 110-pounders, and Nos. 25, 26, two 68-pounders fired together in salvo against the right end of the top plate, were the trying and final test of the programme. The target passed through this ordeal triumphantly. There was the usual indentation from the shots individually, and several cracks over the area of impact, but the smashing effect was less than from similar salvos fired at other targets on previous occasions. The plate buckled outwards at the end about 3 in., the frames inside and the skin were curved full 2 in., and one bolt which was struck on the head was broken in two in the shaft and the end-piece driven through.

---

* An illustrated description of Chalmers' target will be found on page 324.

The trial of this target must be regarded as a remarkable success. It stood the brunt of the firing throughout better than the "Warrior" target. In the crowning test—the salvo of 5 great guns, concentrating 466 lb. weight of metal, at a high velocity against one plate over an area of about 2 ft. square—it carried away the palm. A similar salvo, fired at the "Warrior" section, fractured and buckled the plates more extensively, and broke or loosened six or seven bolts.

The success so far obtained is to be ascribed to the cellular iron-backing, on which the plates are bedded, and no doubt would have been more decided, if the principle of rigidity had been entirely adhered to. The indentation and cracks in the plates would probably have been less, if the wooden cushion and its supporting frames behind the cellular backing, which Mr. Chalmers stated to be the main feature of the plan, had been omitted from the structure. He openly acknowledged his error, and regretted that he had not used the misapplied weight of the cushion to increase the thickness of the armour plates.

In comparing this with the "Warrior" target, it must be borne in mind, that the plates of the former are only 3¾ in., whilst the latter are 4½ in. thick. On the other hand, it must be conceded, that the total weight of materials in the Chalmers structure, exceeds that of the "Warrior" section by 50lb. per square foot, a difference which not only ought to give greater strength, but is an element of importance in respect of the carrying capacity of a ship. For the armoured area of a "Warrior," the additional burden would be about 250 tons. If that weight, equal to 1¼ in. of iron all over, were added to the thickness of the "Warrior" plates, increasing it from 4½ to 5¾ in., their resisting force would be greatly augmented.

This experiment is a practical demonstration on a large scale, of the superiority of rigid, to elastic or yielding backing, of which smaller experiments of the Iron Plate Committee afforded indications two years ago. It may be hoped that the Admiralty will at length learn to believe that the "Warrior" system of armour-plating is not perfection.

Up to this point, which concluded the ordinary test experiments with 110 and 68-pounder guns, no projectile was fired with a force sufficient to penetrate the outer armour plates. The trial so far established the fact that a 3¾ in. plate on a rigid backing has greater force of resistance than a 4½ or 5½ in. plate on wood backing. In this case, it better protected the plates from indentation or buckling, and better protected the fastenings. Practically, it resisted penetration more effectually. But the strength of this peculiar system of constructing cellular backing, to resist smashing effect, was not put to the proof by any of the projectiles hitherto fired. This ordeal was reserved for the last round, No. 27. It consisted of a 300-pounder solid steel shot, fired with a charge of 45 lbs. This formidable missile made a clean breach through and through the target. Having penetrated the armour plate, of which it cut out a piece about 12 in. in diameter, and carried it off bodily on the face of the shot, it met with no resistance from the 4½ in. teak planks an ¾ in. iron plates, which were pounded into small splinters and minute particles. It crushed through the iron skin and frames, forming an aperture in the hull of the ship 18 in. by 2 ft. The shot was then brought up by an old Hawkshaw iron target, which served as a back support, and, although 9 in. thick, was burst open by the spent force.

In former trials of smashing effect with a 300-pounder steel shot and 45 lb. charge on other targets, not exceeding this in weight, the effects were by no means so destructive. The projectile encountered greater resistance. The difference may be accounted for by the want of cohesive strength, before alluded to, in the mode of building up the backing by alternate layers of teak planks and thin iron plates packed horizontally one upon the other, and tied together with vertical rods, for the passage of which numerous holes are perforated through the planks and plates.

This appears to be a defect in the mode of construction which, no doubt, can be remedied. In the meantime, probably, the value of rigid backing to prevent buckling and protect bolts is established by these interesting experiments.

TWIN SCREW STEAMERS.

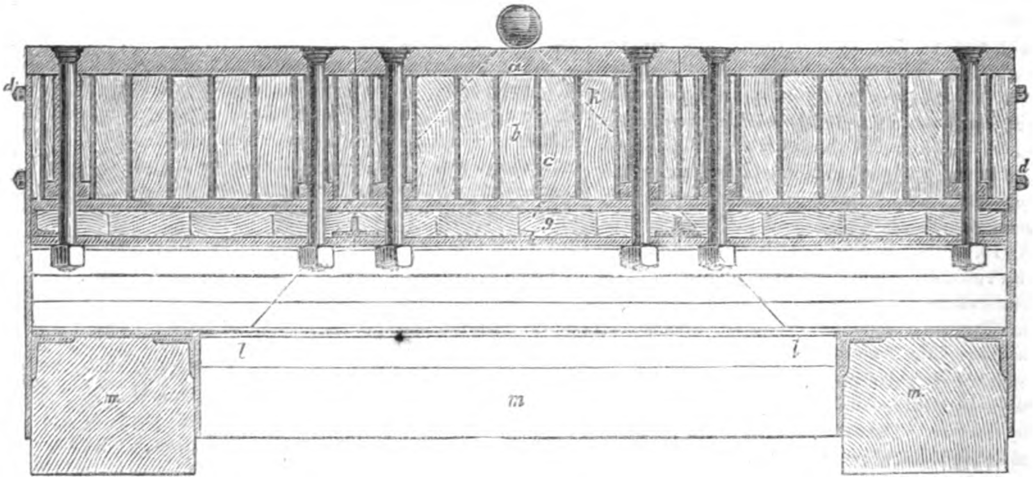
We have several times recently called attention to the plan of building twin screw steamers as patented by Mr. Richard Roberts, advocated by Commander Symonds, and practically tested by the Messrs Dudgeon, of the Isle of Dogs. The subject is an important one, and we are glad to find that it is securing the consideration of scientific men. On Wednesday last week, Commander Symonds read a Paper on the subject before the Society of Arts, and on Saturday last the Messrs. Dudgeon made a trial with the "Hebe" between the Nore and Mouse lightships.

Commander Symonds, in his Paper, said:—Notwithstanding the marked improvement that had taken place in shipbuilding during the last quarter of a century, we did not appear to have made that progress in the application of the screw as a propeller which might have been anticipated; nor had we improved the manœuvring and steering qualities of our ships in the slightest degree, although the necessity for this has increased with the larger dimensions on which they are now constructed. It had been, as the author thought, unwisely recommended to increase the area of the rudder considerably, and apply steam or hydraulic power to actuate it, thus effecting by overwhelming force that which might be attained by turning the propelling power to account as a steering agent. He believed we had arrived at a point beyond which it would be unsafe to increase the size of the rudder. He pointed out various objections that he conceived to exist in the ordinary single screw system. Amongst these might be mentioned the enormous and costly forgings required for stern-posts, and other difficulties of construction, the exposed position of the ordinary screw and its liability to fouling, as well as the fact that, being in the centre of the iron, it works in the centre of the disturbed water or eddy caused by the passage of ships, and, being so near the surface, is constantly lifted out of the water, which involves loss of power, and causes vibration by the unequal action of the upper and lower blade. The invention of the twin or double screw was due to Captain Carpenter, R.N. In this instance, and until a date subsequent to Mr. Roberts's invention, the two screws were driven by the same engine, and therefore could not be used independently, the leading and most valuable feature of the principle being entirely overlooked. This Mr. Roberts supplied by the application of separate engines to each shaft, by which the screws are driven independently of each other, and a perfect steering power is obtained. By reversing the action of one screw the ship is turned round on her centre, as upon a pivot. Commander Symonds mentioned several vessels in America, as well as in this country, particularly the "Flora" and "Kate," that had been fitted on this system, and adduced instances in which they had displayed remarkable powers of manœuvring. He described in detail the particular mode of construction which he recommended, and said that he had made most important improvements since the two vessels above mentioned were constructed. He pointed out the great advantages, particularly in warlike operations, that his system afforded, and he thought that from whatever point of view it might be regarded, whether as a power of propelling, steering, or manœuvring our otherwise unmanageable war ships, either engaged at sea or with forts in narrow waters, or whether as applied to ships of commerce, where light draught and handiness are equally essential, the question assumed a magnitude and importance that demanded the greatest consideration and the most ample experiment.

The trial which took place on Saturday last was the third of the kind which the Messrs. Dudgeon, had made.

The performances of the first two—the "Flora" and the "Kate"—have been already noticed, and the advantages of the system over that of the single screw were again strikingly manifested during a series of manœuvres which were made after the trial of speed between the lightships. The "Hebe" is an iron vessel, of 470 tons, 165 ft. long, 22 ft. 6 in. beam, 13 ft. 6 in. deep, having a deck house, 7 ft. high, extending about three-fourths of her length, fitted up with cabin and saloons. Draught of water at time of trial, 5 ft. forward and 9 ft. aft. Being without dead weight to give her sufficient immersion, the vessel was under considerable disadvantages, especially as there was a strong wind blowing, which materially retarded those evolutions which formed the principal feature of interest to most present. The screws were three-bladed, 7 ft. 6 in. in diameter, with 15 ft. pitch, worked by two separate and independent engines, having two cylinders 26 in. in diameter, with 21-in. stroke of pistons, and 120 collective nominal horse power. The revolutions at the time of trial between the lightships were 110. The time occupied between the Mouse and Nore light-ships was 33 min. 15 sec., the distance being eight statute miles. Among the evolutions performed for the satisfaction of the scientific gentlemen present were the following:—1. Full speed ahead with both screws, helm hard a starboard; circle complete in 4 min. 2. Full speed ahead, both screws, helm hard aport; 3 min. 40 sec. 3. Helm a starboard, with port screw stopped; circle completed in 3 min. 9 sec. 4. Circle made the reverse way by putting the helm aport and with starboard screw stopped, in 3 min. 38 sec. 5. Helm hard aport, the screws being turned in opposite directions, the vessel pivotted on her centre in 3 min. 52 sec. 6. A second experiment the reverse way was made in 4 min. 10 sec.; the mean time of these last two revolutions being 4 min. 1 sec. 7. Helm amidship, the screws working in opposite directions; the circle was completed in 4 min. 58 sec. The engines varied alternately in these trials from 90 to 103 revolutions per minute. As before mentioned, during these experiments a fresh wind prevailed, which materially retarded the turning, the vessel being light, and consequently exposing a large area to the wind. The engines worked admirably throughout, the boilers giving an abundance of steam, and the whole of the arrangements were excellent, reflecting great credit on the builders. Among the numerous scientific gentlemen present were Sir J. D. Elphinstone, M.P., Admiral Sir Edward Belcher, C.B., Sir J. Lawrence, Captains Jones and Howes, R.N., Commander T. E. Symonds, R.N., Colonel Paradis, (Imperial Austrian Service), Messrs. W. Ellice, E. Gellatly, F. Sewell, Abbots, Dunbar, O. Dingler, Imperial Austrian Service, W. Smith, C.E., Zerah Colburn, C.E., Kitson, C.E., and others connected with the mercantile marine.

THE CHALMERS' TARGET.



THE CHALMERS' TARGET.

This target, which proved such a signal success at Shoeburyness, on Monday last, represents a section of an iron-plated ship, 13 ft. 4 in. by 10 ft. The accompanying cut is a vertical section of the target, from which it will be seen that its chief distinctive features are—first, the backing to the armour plate *a*, composed of alternate layers of timber planking *b*, and iron ribs *c*, which present their edges as a support to the plates, and which are bolted together laterally with the bolts *d*; second, an intermediate or second armour plate *f*, being, as it were, a back, or bottom girder, upon which the inner edges of the backing layers rest; third, a cushion of timber planking *g*, between this second plate and the skin of the ship *h*; fourth, the through fastening-bolt *i* has a stepped conical neck, and a peculiar square thread, the depth of which is only half the pitch. The inventor states that the objects aimed at in these arrangements are to obviate the evils that invariably result from a backing composed of wood only, such as buckling, penetration, &c., and to guard against the equally injurious effects of vibration and distortion, such as the fracturing of the armour plates and the destruction of fastenings and frame of ship, which he contends are inseparably connected with very rigid structures. Mr. Chalmers has long maintained that his plan of construction is calculated to disperse over an extended area the power or work contained in the projectile at the point of impact, for, owing to the great strength of the compound backing *b*, *c*, he argues, that the force will take the direction of the diverging lines *k*, thus giving an area of resistance equal to 25 ft. at the inner line of the ship's frame *l*. The results of the trial on the 27th show how well founded have been his calculations. The importance of the old "Warrior" target as a standard of resistance has passed away, and "The Chalmers' Target," for the present, will be the datum from which to estimate the value of future projects.

COOKE'S IMPROVEMENTS IN BATTENS FOR WEAVING.

FIG. 1

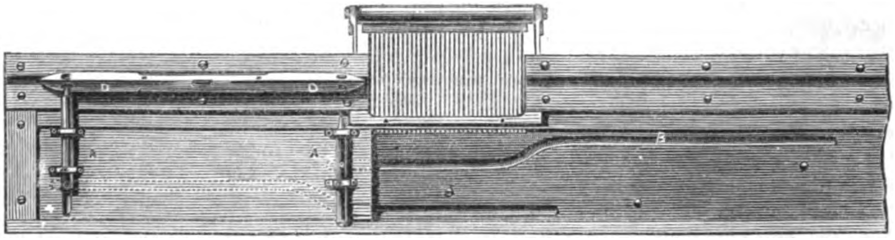


FIG. 2

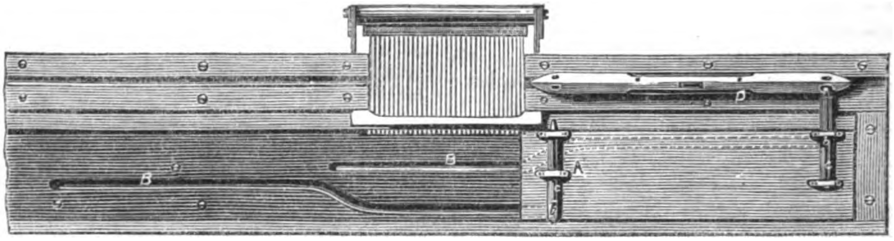

FIG. 3

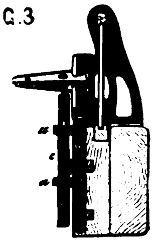

FIG. 4

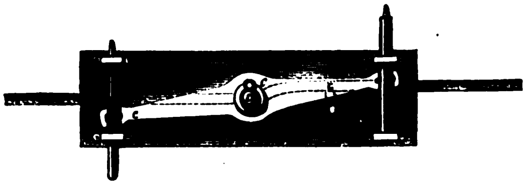


IMPROVEMENTS IN BATTENS FOR WEAVING.

Mr. J. T. Cooke, of Leicester, has obtained a patent for "improvements in battens for weaving." The invention consists in the employment of one slide bar or carrier, on which are fitted pegs or bolts for carrying the shuttles from side to side of their work, as hereafter described. Fig. 1 of the accompanying engravings is a face view of a batten, constructed according to this invention, showing the shuttle on one side of the race; and fig. 2 is a similar view, showing the shuttle on the other side of the race. On the bed of the batten a slide-bar or carrier A is fitted, which works in grooves B, B, so that it may slide backwards and forwards. On this slide-bar are fitted pegs or bolts C, C, working through eyes *a* to allow the pegs to rise and fall. On each of the pegs C a stud *b* is fitted, as shown in section in fig. 3, which studs pass through the slide-bar A and work in the grooves B, B. The slide-bar A has slots *c* cut therein for the studs *b* on the pegs C to work through; the studs *b* fit and work in the grooves B, B, so that when the slide-bar A is moved to and fro the pegs C receive an up-and-down motion, and take alternately into the holes in the shuttle D, which is thereby carried from side to side of its work.

The motions of the pegs are obtained by means of a balance lever working on an axis fixed on the slide, as shown in fig. 4, which is a face view of the slide-bar. A is the slide-bar; B the groove, of which there is only one in or on the bed of the batten, and of the shape shown; C is the balance lever centered on the axis D fixed in the slide-bar. Slots E, E are formed in the arms of the lever, and these slots receive studs fixed on the pegs F, F. G is a guide-pin fixed in the balance lever, passing through the slide-bar and entering the groove B. On the slide-bar being driven from end to end of the bed of the batten, the lever is caused to rock, and drive the pegs into and out of the holes in the shuttle, and thus carry it through its work.

INSTITUTION OF CIVIL ENGINEERS.

April 28, 1863.

John Hawkshaw, Esq., President, in the Chair.

The Paper read was, "The Charing-cross Bridge," by Mr. Harrison Hayter, M.Inst.C.E.

It was stated that this bridge consisted of nine spans—six of 154 ft. and three of 100 ft.—the centre opening of the Hungerfod Suspension-bridge having been divided into four spans each of 154 ft., and that on the Surrey side into two spans also of 154 ft. each, and the opening on the Middlesex side into three spans, each of 100 ft.—the superstructure over the latter being fan-shaped. The width of the river, at the site of the bridge, was 1,350 ft. The greatest depth of water between the two brick piers of the original bridge was 13 ft. below low-water spring tides, and the average depth was about 9 ft., the the rise of spring tides being 17½ ft. The level of the rails was 31 ft. above Trinity high-water mark, and there was a clear minimum headway under the bridge of 25 ft. above the same datum.

The superstructure was carried by cylinders sunk into the bed of the river, and by the piers and abutments of the suspension-bridge, the abutments having been considerably lengthened. The cylinders, excepting at the fan end, were 14 ft. diameter below the surface of the ground, and 10 ft. diameter above, the junction between the two sizes being effected by a conical length. There were four piers formed of these cylinders, each consisting of two cylinders, 49 ft. 4 in. apart from centre to centre. They were of cast iron, 1⅛ in. in thickness throughout, and the circumference was divided into segments, with interior flanges round all the edges, through which the segments were bolted together; and a horizontal interior rib was also cast in the middle of each segment. There were thus continuous vertical lines of ribs, securing a strong columnar arrangement.

The strata through which the cylinders were sunk consisted of mud and gravel, of varying thicknesses, overlying the London clay. The sinking was effected by excavating the material from the inside—at first by divers, but after the London clay was reached and the water pumped out, in the ordinary way—and by weighting the cylinders, to an average load of 150 tons each. These cylinders were sunk to depths of 52 ft., 62 ft., and in one case 72 ft., below Trinity high-water mark. They were filled with Portland cement concrete up to where the conical length commenced, and above with brickwork, set in Portland cement mortar, to the under side of the granite bearing blocks, which were 2 ft. 6 in. in thickness, and projected 1 in. above the top of the cylinders, in order that the weight might not come on the upper edge of the ironwork. With a view of testing the strength of the foundations, the two cylinders in the pier nearest to the Surrey side, after being completed up to the level of high water and filled with concrete and brickwork, were each weighted with 700 tons, being about equal to the greatest load they could possibly have to sustain, supposing the four lines of rails on the bridge to be loaded with locomotive engines. This caused the cylinders to sink permanently 4 in. To bring the other cylinders to a bearing, so as to prevent any settlement after the completion of the bridge, from the weight of the permanent and moving loads, they were each weighted with 450 tons, when it was found that they permanently sank, on an average, 3 in. each. Each pair of cylinders forming a pier was connected together transversely by a wrought-iron box girder, 4 ft. deep, which also served as a cross-girder for supporting the roadway. Assuming the four lines of way on the bridge to be loaded with locomotive engines, the pressure on the base of the cylinder would amount to eight tons per square foot, and on the brickwork at the top of the cone to about 9 tons per square foot.

The superstructure of each of the 154 ft. openings consisted of two main girders, to the under side of which were suspended cross-girders, for carrying the roadway platform. These cross-girders extended beyond the main girders, and formed a series of cantilevers on the outer sides, for supporting two footpaths, each 7 ft. wide in the clear. The main girders were of wrought iron, and were not continuous, but extended only over one opening. Each girder had to support, inclusive of its own weight, a maximum distributed load of 750 tons. The extreme depth of these girders was 14 ft., and the depth between the centres of gravity of the top and bottom members was 12 ft. 9 in. The sides of the girders between the bearings were divided into fourteen equal parts by a pair of vertical bars, connected to the top and bottom by pins of puddled steel, 7 in. diameter at the ends of the girder, decreasing to 5 in. diameter at the centre; and each division contained a double set of two diagonals crossing each other. The top and the bottom of these girders were of boiler-plate, and consisted of horizontal tables 4 ft. and 3 ft. wide respectively, and of four vertical ribs, the two outer rows being 24 in. deep, and the two inner rows 21 in. deep. The aggregate thickness of the plates in the horizontal table of the top in the centre of the girder was 3⅛ in., and in the bottom 3 13-16 in., without the angle irons, and of 4⅛ in. and 4 13-16 in. respectively with the angle irons, but exclusively of the angle iron covers. It was arranged that, with the greatest load, the maximum strains should not exceed 4 tons per square inch in compression, and 5 tons per square inch in extension. All the rivet holes were drilled by machines capable of drilling several holes at one time. This plan was, under the circumstances, less costly than punching, besides which a great saving was effected in putting the work together. The diagonals acting as ties were of Howard's rolled suspension links, each separate tie being composed of two or three links, as required, riveted together. The diagonals acting as struts were each in one solid forging, and were united together in pairs by zig-zag bracing of wrought iron. In the centre of the girders, where the diagonals acted as both struts and ties, the pairs were united together in the two central spaces by the zig-zag work. The dimensions of the struts varied from 12 in. by 3 in. at the ends to 6 in. by 2½ in. in the middle, and of the ties from 12 in. by 2⅛ in. at the ends to 6 in. by 2 in. in the middle. The ends of the girders over the piers were boxed in, with plates ⅜ in. thick, stiffened by angle and T irons. Over the cylinders the girders rested on sheet lead, laid upon the granite blocks. On the brick piers and the Surrey abutment, they rested upon roller bed-plates. The girders were put together in place on a staging, the upper and lower platforms of which were accurately adjusted to the proper camber. The whole of the plates were drilled, and the struts and ties were completed, before being sent to the works. The weight of each main girder was 190 tons. One of the main girders was tested when in its place with a distributed load of 400 tons, when the greatest deflection observed was 1 5-16 in., and the permanent deflection after the load was removed was ½ in.

The cross-girders of the 154 ft. openings were of wrought iron, and were generally similar in character to the main girders, from which they were suspended, at intervals of 11 ft. apart, from centre to centre. They were 4 ft. deep in the middle, and 2 ft. 1⅛ in. deep where the cantilevers were united to them outside the main girders. The top and bottom consisted of two plates, 18 in. wide by ⅝ in. thick, the sides being of lattice bars united to the top and bottom by angle irons. The cantilevers decreased from 2 ft. 1⅛ in. deep at their junction with the cross-girders to 1 ft. 2 in. deep at their extremities. Each cross girder, including the two cantilevers, weighed 9 tons. When two of these cross girders, without the cantilevers, were tested with a load of 140 tons, equivalent to 70 tons on each girder, the maximum deflection in the centre was 1 in., and the permanent deflection when the load was removed was ¼ in.

The superstructure of the three 100 ft. openings of the fan end was supported by the brick pier and abutment on the Middlesex side of the suspension bridge, and intermediate to these by two rows of seven and of nine cast-iron cylinders, respectively. These cylinders were 10 ft. diameter below the ground level—the outer ones being 8 ft. diameter, and the inner ones 6 ft. diameter above that level. They were sunk to depths averaging 40 ft. below Trinity high-water mark, and were filled with Portland cement concrete to about 5 ft. above that level; but it was not considered necessary to fill in the remaining portion of these cylinders. On account of the great width of the fan end, which increased from 49 ft. 4 in. at the brick pier to 168 ft. at the abutment, the plan of supporting the roadway on cross-girders, suspended from outside main girders, was inadmissible; and as it was not desirable to introduce intermediate main girders, projecting above the line of rails, the roadway was carried by interior plate girders, laid at right-angles to the piers and abutment, and by the outside main girders, which were laid at the angle of inclination of the fan. The outside main girders were of the same depth, and were generally of the same character, although lighter in all the parts, and were fixed at the same level, as the girders of the 154 ft. openings. The interior plate girders were of the ordinary construction, 5 ft. deep, or 1-20th of the span, and weighed 26 tons each. The triangular spaces between the outside main girders and the outer interior plate girders were filled in with cross girders, terminated by cantilevers, projecting beyond the face girders, and similar to those outside the main girders of the 154 ft. openings.

The roadway platform over the 154 ft. openings consisted of planking 4 in. thick, spiked to longitudinal timbers, 15 in. by 15 in., placed underneath the rails, and bolted to the cross girders. Over the fan end, the platform consisted of planking 6 in. thick, secured to the girders. The footpath platforms were of planking 6 in. thick.

The first cylinder of the Charing-cross Bridge was pitched on the 6th of June, 1860, and as the bridge was now on the eve of completion, its construction would thus extend over a period of about three years. The weight of wrought iron in the bridge, including the steel pins, was 4,950 tons, and of cast iron 1,950 tons. The total cost, including the abutments, would be £180,000, or £1 15s. per square foot, and £131 per lineal foot. The cylinders of the 154 ft. openings cost complete £20 per lineal foot; the outer cylinders of the fan end cost about £12, and the inner ones about £10 per lineal foot. The bridge was designed by Mr. Hawkshaw (President Inst.C.E.), the Engineer to the Charing-cross Railway Company, and was carried out under his immediate supervision, Mr. John H. Stanton (M. Inst. C.E.) being the resident engineer. Mr. George Wythes was the contractor for the construction of the railway, but this bridge was sublet to Messrs. Cochrane and Co., whose representative on the works was Mr. Joseph Phillips (Assoc. Inst. C.E.)

ATMOSPHERIC TRIP HAMMERS.

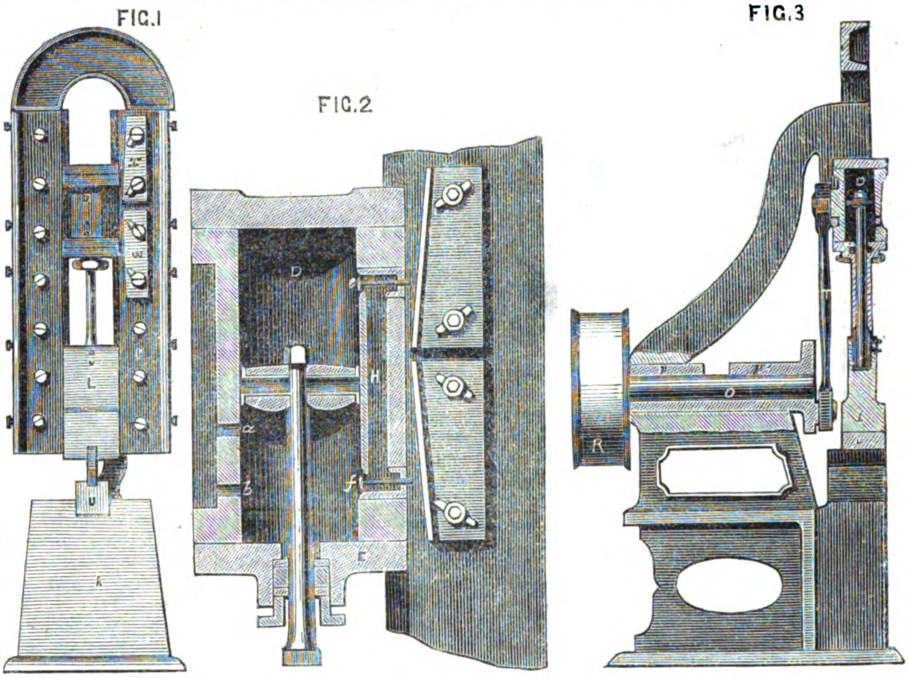
Mr. B. Hotchkiss, of New Haven, U.S.A., has recently patented an improvement in atmospheric trip hammers.

The frame consists of two parts, whereof the lower forms a bed to which the upper is bolted, an elastic substance being inserted under the washers of the nuts in order to lessen the effect produced by the blow of the hammer. The hammer is worked by means of an air cylinder, to which is imparted a vertical reciprocating motion. Within this cylinder is fitted a piston, to the rod of which the hammer is connected, the rod being enlarged at the part where the connection is formed in order to prevent the liability of its being broken. The atmospheric air is admitted into the cylinder through apertures so placed as to allow the air to pass thereinto at such periods as to cause it, by compression, to act as a spring between the piston and the lower end of the cylinder on the upward motion of the latter, and to impart an impelling force to the piston in a downward direction on the downward motion of the cylinder; or, instead of such apertures, two valves are fitted—one at the upper part of the cylinder, and the other at the lower part—with an air passage communicating between them, the rods of such valves being acted upon by coming in contract with adjustable inclined planes fixed on the side frame of the apparatus. The object of both these arrangements for admitting the atmospheric air to the cylinder is to regulate the force of the striking power imparted to the hammer without altering the speed of the driving shaft.

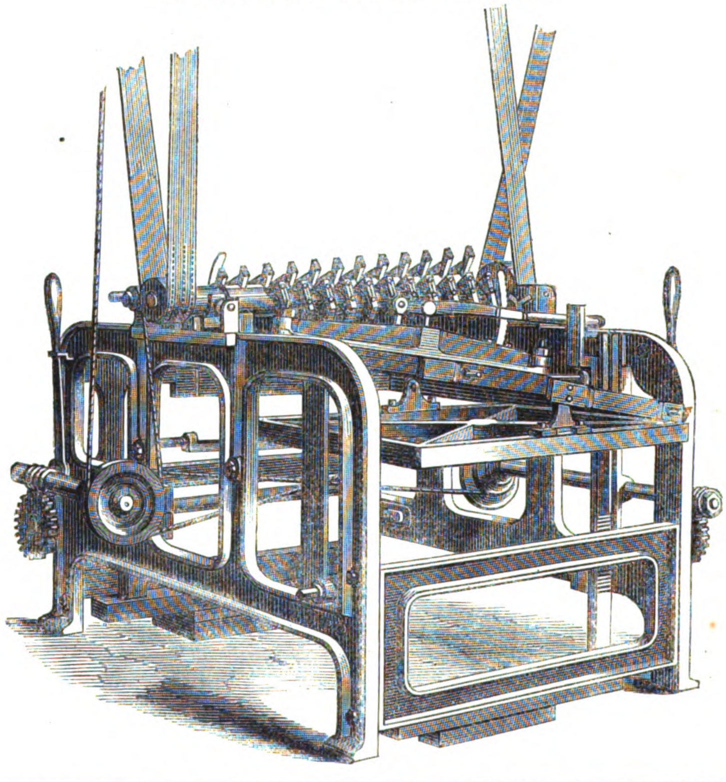
A is the lower frame, upon which the upper parts are supported. The upper frame B is so constructed as to form guides to receive and guide the air spring cylinder D; air passages *a*, *b*, are formed in the side of the cylinder, which passages are open to the external air. Instead, however, of these open passages, two valves *e*, *f*, may be inserted in the side of the cylinder or valve chest attached thereto, operated by adjustable mechanism. These valves should be placed near the ends of the cylinder to allow the stroke to be varied to a considerable extent, though not so far as, in any case, to prevent the blow from being cushioned so as to prevent damage to the to the parts. H is an air passage which connects the openings which contain the valves *e*, *f*, and is intended to allow the air which may be forced out of the cylinder at one end to pass into the other end of the cylinder, so that no loss may be occasioned, and no outside communication is in this case necessary. The piston is arranged within the cylinder, and has its rod extending through the lower head of the cylinder, and attached to the hammer L. O is the driving shafts which has its journals supported in boxes P, P. A pulley R is attached to this driving shaft, and at the opposite end of the shaft a crank wheel is fixed, in which a pin is inserted, and extends through the connecting rod T, the upper end of which is by a similar pin connected to the cylinder D. By applying power to the pulley R, motion will be imparted to the shaft O, and thence, through the connecting rod T, reciprocating vertical motion will be given to the pneumatic or air spring cylinder D, and in consequence thereof the hammer will be lifted and forced downwards towards the anvil U, or any article placed thereon. During each elevation or depression of the cylinder the piston will pass by the air passages *a* and *b*, and compress all the air that may be in the cylinder between the piston and the cylinder head. This compression of the air while the cylinder is descending will act as a spring to overcome gradually the inertia of the hammer, and prevent the piston from coming in contact with the lower head of the cylinder; so during the descent of the cylinder the air will be similarly compressed in its upper part, and will in like manner relieve the cylinder head above from the shock of the blow. The quantity of air compressed in the cylinder materially affects and controls the stroke of the hammer, and it will be obvious that by closing the lower hole or passage *b*, and opening the upper, a quantity of air to compress below the piston will be equal to the contents of the cylinder below the upper opening *a*; but by leaving the opening *b* open, the stroke is thereby reduced, as a less compression of air takes place, as it is obvious that the hammer will not be raised until the piston is met by the air below it in the cylinder, and that the cylinder produces no material effect upon the hammer between the points at which the air is left free to escape. This change, by means of a series of openings in any ordinary work not largely variable, may be sufficient for the purpose desired, but where a still greater range of variation in the stroke of the hammer is necessary, the valves *e*, *f*, may be employed. These valves open inward, and the operation of opening them is performed by the stems striking against the adjustable inclined planes W, X, which are fixed upon the frame for that purpose. These valves may be usually kept closed by spiral springs, or otherwise, as may be desirable.

A steam digging machine, invented by a French firm, has been successfully tried on the Emperor's model farm at Vincennes.

HOTCHKISS'S ATMOSPHERIC TRIP HAMMERS.



BURLEY'S DOVETAILING MACHINE.

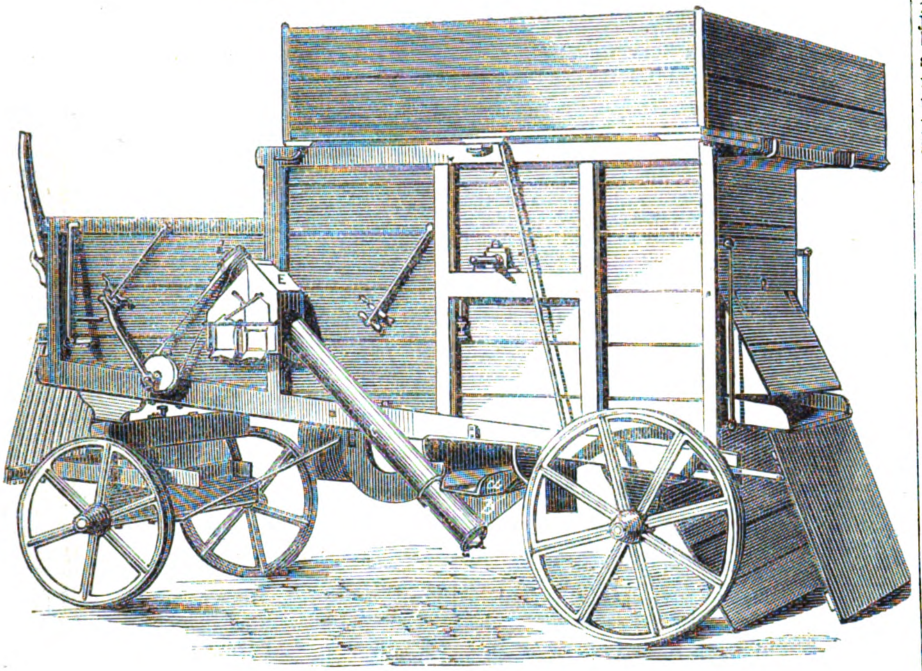


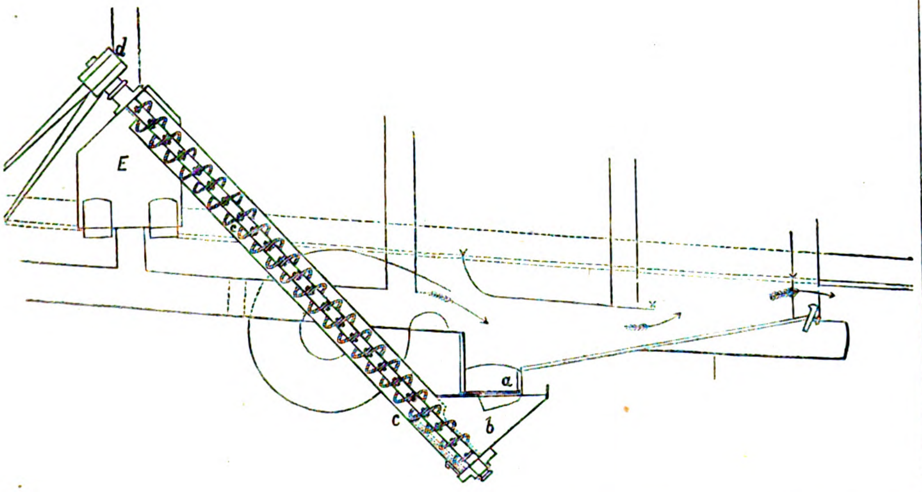
THE BURLEY PATENT DOVETAILING MACHINE.

This machine may be seen working at Messrs. E. Spencer and Co.'s Packing Case Factory, Billiter-steet, E.C. It is the invention of Mr. Thomas H. Burley, of New York, and consists of two rapidly revolving shafts, furnished by means of arms with cutters disposed at equal distances. On one shaft these cutters are disposed in the form of a cone, and on the other shaft at equal distances from its centre. The wood to be operated upon is placed on a rising and falling table, with the end to be dovetailed parallel to the edge of the conically disposed cutters, and is held in that position by a lever and clamp. Motion is given to the table by the side handle, and it rises until it reaches the centre of the cutter shaft, when it trips itself and falls; the wood is then turned over, and on the same operation being repeated, the mortises are completed ready for use.

The "pins" are made by the plain cutters, but in order to make a bevel corresponding to the mortises, the table on which the wood is placed is made to tilt both ways, and rises against the cutters, first on one angle and then on the other, and by these means completing the pins. The depth of mortises and length of pins is regulated by set screws, which admit of easy adjustment.

WATTS' COMBINED THRASHING MACHINE.





ADAMS' IMPROVED SLIDE VALVES.

FIG. 1

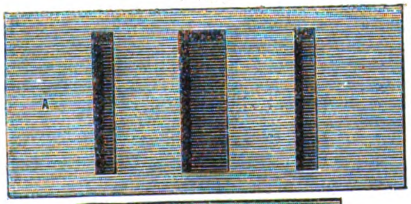


FIG. 5

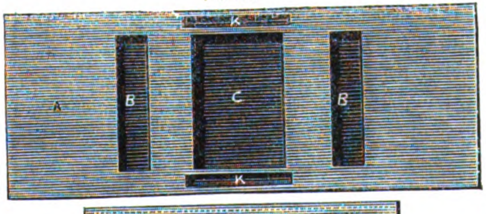

FIG. 2

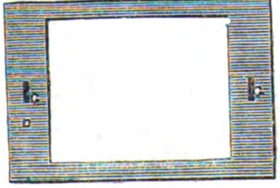

FIG. 4

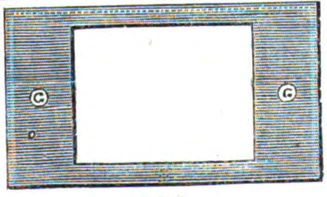

FIG. 3

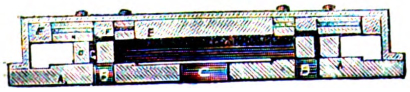

FIG. 6

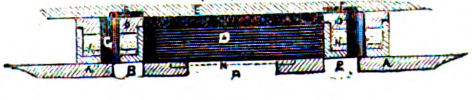


WATTS' COMBINED THRASHING MACHINE.

MR. T. WATTS, of Carisbrooke, Isle of Wight, has just obtained a patent for "improvements in combined thrashing machines," The invention consists of forming a screw, the thread of which is made of thin iron plate. This screw revolves in the inside of a sheet-iron cylinder, and is for the purpose of elevating and dressing corn and other grain.

The annexed engravings shew a view of the machine with elevator and appendages attached, and a detached view of the elevator in section. *a* is the shute which conducts the corn to the lower hopper, which is fitted with a perforated bottom, thereby forming an extra riddle to carry the short straws or ears over the hopper and drop them on the outside; *b* is the lower hopper, which is fitted with a slide and opening in order to let all grain out of the cylinder when finishing; *c*, the cylinder through which the grain is elevated and dressed; *d*, the pulley on screw spindle which gives motion to screw inside of cylinder, receiving its motion by means of a rectangular band or strap; E, the delivery box, to which bags or sacks are hooked to receive the corn or other grain.

ADAMS' IMPROVED SLIDE VALVES.

THE improved slide valve illustrated in the above engravings has been recently patented by Mr. T. Adams, of Deptford. The object of the invention is the production of an equilibrium of the steam, fluid, or gaseous pressure on the valve by causing the steam, fluid, or gas to act with equal pressure on opposite sides of the valve at the same time, thereby obviating the loss of power caused by the unbalanced pressure on the valves as they are ordinarily constructed and arranged. For this purpose recesses are formed in the door or front of the slide valve box, or in the valve, in such situations as to admit of the steam, fluid, or gas passing at the same time to opposite sides of the valve. There are also passages through the valve so as to form communications between the ordinary ports leading into the cylinder, and the recesses or false ports. By this arrangement the pressure on the valve of the steam, fluid, or gas, as it enters or escapes from the cylinder through the ordinary ports, is balanced by the pressure of the same on the opposite part of the valve, thereby effecting a constant equilibrium of pressures on the valve.

Fig. 1 is a plan of the cylinder face, and fig. 3 is a section through the valve, valve box, and cylinder face. A is the cylinder face; B, B, are the ports communicating with the cylinder; C, is the exhaust port; and D, is the slide valve, which is cut out in the central part, as shown, leaving only a frame of metal. It will also be seen on reference to fig. 3, that the valve fits the space between the door E of the valve box and the cylinder face, so as not to admit of steam pressing the valve on to the cylinder face, except in the false ports F, F, oppposite to the ports B, B, where the pressure is balanced by that in the latter ports. G, G, are the communications between the ordinary ports B, B, and the false ports F, F, through the valve. H, H, are plates between which suitable packing is placed, in order to give elasticity to the plates against which the valve works. The steam from the boiler is caused to press on the opposite ends of the valve at the same time, thereby producing an equilibrium of pressures on the valve in the horizontal direction, also that the pressure of the steam in the ports B, B, will be balanced by that in the false ports F, F, the steam being free to pass from the former to the latter, and causing an equilibrium of pressures on the valve in the vertical direction. The exhaust also acts equally on the inner sides of the valve.

In figs. 4, 5, and 6, the same principle of constructing slide valves, so as to effect an equilibrium of pressure thereon, in working is shown; but in this case the valve is divided into two parts (which may be termed the male and female portions of the valve) with packing inserted between them. The only difference between this construction of valve and that above described is that, whereas in the former instance the valve was in one piece, with the packing inserted in the door of the valve-box, in the present instance the valve is divided into two parts D D, with the packing inserted between them. Owing to this mode of constructing the valve, there will be a space all round it, in which there will be a pressure of steam having a tendency to force the upper portion against the door E, and the lower portion against the cylinder face A. In order to balance this pressure it is necessary to form recesses K, K, both in the door E and the cylinder face A of an area equal to that of the space round the valve. There is a passage for steam into the recesses formed either in the valve, or the cylinder face, or the door. Should it be required to apply pressure on the valve for the purpose of keeping it on its face, any required amount of pressure may be applied thereto by making the recesses less in area than the space round the valve.

THE LATE MR. JAMES FENTON, C.E.

ANOTHER old name in the engineering world has departed. Mr. Fenton, of Low Moor, after a very protracted illness, died at Leamington, on the 22nd ult., at the early age of 47. We said an old name; for though a young man, Mr. Fenton very early secured a first-class position in the railway world, which he retained till his death. After leaving the Glasgow University, Mr. Fenton was for some time employed, under Brunel, on the Great Western Railway, which was then being constructed. We next find him on the Leeds and Thirsk line; after which he became the Locomotive Superintendent of the Lancashire and Yorkshire Railway. Some 17 years ago he left the service of that company to undertake the management of the Railway Foundry, Leeds; among the various works he executed while in that position may be mentioned the Jenny Lind class of engine—a class possessing great simplicity, and combining steadiness with speed; so highly were these engines thought of on some lines, that they became adopted as the type for all their passenger engines. On one line, the Midland, nearly the whole of their passenger engines were, until they were compelled a few years ago to make a heavier engine, of the Jenny Lind class. Mr. Fenton, also when at the Railway Foundry, constructed and launched one of the largest landing-stages in the kingdom, that at New Holland, where the passengers by the Manchester and Sheffield Railway cross to Hull. Some ten years ago Mr. Fenton became consulting engineer to the Low Moor Company, a position of the highest standing, which he retained to his death; and here he had ample opportunity of meeting all engineers of high reputation, and this soon brought him a very large practice. As a witness he had great powers of explaining mechanical details in a popular style; his last professional engagement was from the War Office. He was appointed by the Government to settle the question of compensation to the Elswick Company. During the attendance on this business in London he caught a severe cold, which hastened his end. Mr. Fenton was a well-known and valued member of the Institution of Civil Engineers, and for many years had been one of the vice-presidents of the Institution of Mechanical Engineers, in the management of which he took an active part. Mr. Fenton's loss will be much felt by many of our young engineers. He was always ready with his advice and assistance; and it may be truly said that he left no enemies behind him. Mr. Fenton was buried at Low Moor on Monday last, and was followed to the grave by Messrs. Wickham and Hardy, the managing partners of the Low Moor Iron Company, Joseph Freeman, and many of his old friends—Messrs. Wilson, of the West Midland; Kirtley, Fernie, Pettifer, and Alton, of the Midland; Johnson, of the Manchester, Sheffield, and Lincolnshire; Brown, of the Edinburgh and Glasgow. Mr. Fenton leaves a widow, two sons, and three daughters to lament his loss.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

APRIL 23rd, 1863.—Francis Campin, President, in the chair.

"ON MARINE SURVEYING."

By Frederic E. Cooper and G. J. Crosbie Dawson.

AFTER a suitable preface, Mr. Dawson, who read the Paper, went on to say:—As necessarily the greater part of these operations would be carried on in the water, it will be obvious that a safe and manageable means of transit will be of importance, varying of course with the requirements of the place. When there is but a little current or tide, a two-oared boat will generally be found sufficient; but when the tide runs strong or there is a heavy current, the number of oars must be increased, for facility of motion is greatly required. Very often when surveys are made in the open sea, a steamboat is advantageously made use of.

The instruments that will be necessary are a box-sextant and a sounding line. It will be unnecessary here to give a description of the box-sextant, most being conversant with its construction and uses. The sounding line should be of stout cord, and should be marked while wet in fathoms, by means of strips of leather, according to the number of fathoms. The lead should be about 9 lb. weight, somewhere about 1 ft. long, about 2 in. in diameter at the lower end, and 1 in. at the top.

In sea sounding and where it is desirable to ascertain the nature of the bed, the common practice is to have what is termed the dead-eye in the lead, which is a small cavity in the bottom, 2 in. deep, filled with tallow, to which the substance forming the bed adheres.

Where the depth does not exceed 12 ft., a sounding pole is useful, and will be found more manageable than the lead. This is a rod of light wood about 1¼ in. in diameter, marked in feet and inches, with a flat piece of wood at the bottom to prevent its weight forcing it into the mud, and thus giving a false sounding.

In tidal waters the tide gauge is of great importance. It is a board marked plainly in feet and half feet, of a sufficient length to take in the rise of the tide. This should be fixed at some convenient spot not too exposed, yet capable of marking the rise of the tide accurately; its zero should be fixed to some convenient datum, such as low water spring tides—and during the time that soundings are going on, this gauge should be watched by an attendant, and the successive rise of the tide noted with the exact time, usually at intervals of ten minutes.

In surveying rivers and foreshores, the most usual method of obtaining a correct idea of the course of the bed is by sounding lines at right angles to the course of the river or shore, sufficiently near to each other to ensure correctness in result. To do this, we first mark out on each bank or on the shore the lines intended to be taken by means of flags, ascertaining their position by measurement from objects before obtained; then fix upon one or two known points, or if there are none suitable plant a flag at a distance about equal to half the length of the line to be sounded on either side of it, for the purpose of intersection—a church tower, prominent house, or windmill, &c., will answer the purpose very well.

If circumstances suit, we now proceed to sound. The best time for doing so is usually at low water, or a little before or after. The boat should contain the necessary number of oarsmen, and a steersman who might also "keep the book," for the principal will have to take the angles, which he will find quite enough to do; and as everything depends upon the position of the sounding, great accuracy here is of importance; there must also be a reliable person to take the soundings, one not apt to make a mistake of a fathom, as nothing is easier to do, and such a thing, of course, renders the work of very little use, for it ought with due care to be correct to 6 in. In sounding with the lead, the depths will frequently be between two of the fathom marks, therefore when a sounding is taken, the line should be grasped by the forefinger and thumb at the water mark, while the other hand holds the nearest fathom mark to the sounding rod, by which means the correct reading can easily be seen.

Now, having started our boat, we get into the line to be sounded by careful rowing and steering, a result which is known to be arrived at when the two flags on both sides are in line, or as it is termed "on." The word is now given to proceed: the boat is rowed slowly and steadily in the line to be sounded; the sounder commences his work, throwing in the line as fast as possible, and calling out each successive depth distinctly, which is immediately booked. The person who takes the angles does so as fast as he possibly can, taking them, of course, between the line sounding and the object, or flag put in, for the purpose of intersection; he calls them out as soon as taken, and they are booked, as well also as the time, and the depth of the soundings taken at that time. The book should be divided into five columns, viz., 1st, the angle; 2nd, the time; 3rd, the sounding; 4th, the tide gauge; and 5th, the reduced depths for plotting, and should read thus, say, 22° 30′; 12.25; 15 ft.; 4 ft. 6 in.; 10 ft. 6 in. The figures for the tide gauge are obtained afterwards, and put down in the book to the proper time; the depth on the tide gauge being subtracted from the sounding, gives the reduced result above the datum. Thus the work proceeds until the river is crossed, or until a sufficient distance has been sounded.

In order to check the work as it proceeds, it is usual occasionally to take an angle on each side of the line, and then if the three lines meet in one point on the plot, there is no doubt as to the accuracy of the work. The distance between each angle taken should vary with the bed of the river; sufficient should be taken so as to be able to delineate it accurately; the deepest and shallowest sounding should, in all cases, be fixed by an angle, and the soundings should be taken continuously to guard against shoals and holes being overlooked.

When a marine survey is being made of a considerable extent, such as of a bay, frith, or channel, &c., we require a little more diversity in the lines sounded; great help will be afforded if there are buoys or definite points where the survey is to be made. These should be accurately laid down on the plan, by intersecting them from two or more known points on shore, by means of a theodolite. If there are no definite points, it is sometimes advisable to improvise something of the sort, by mooring casks, &c., where required. Buoys and floating points should be intersected at high or low water, as the water then is nearly still, for as their moorings are necessarily long, there is a considerable difference in their positions at various states of the tide. It is best to intersect at high water, for the mooring then is nearly vertical. Having fixed the points, we should take soundings between them; in the case of buoys marking the deep water channel, it is absolutely necessary to sound in their direction.

In making a marine survey of a coast, where there are no particularly defined points from which to measure, in order to set out our lines to be sounded, a very convenient method is to measure a base along the shore, driving stakes at distances which the lines to be taken are desired to be from each other, usually about 100 ft.; at each of these points we can set out by means of a theodolite and flags the lines themselves.

Hitherto we have only considered marine surveying with regard to water; that is, sounding. We shall now proceed to mention a few methods by which, what we may term periodically dry land, such as shoals which are alternately covered by water and laid bare, are surveyed. Those parts which are dry at low water and are of sufficient consistency to bear walking on, are best surveyed by landing on them at dead low water, fixing points on them by means of angles to the shore, and rapidly surveying them in the usual manner, by running lines round with the chain, judging and sketching-in the offsets.

When the nature of the soil is so soft as to preclude walking on, you must run your boat as near as possible, and fix the main points by means of angles, and then sketch in the form of the shoal between. Here great expedition is required; and great care should be taken with the time and tide-gauge, for the tide rises very fast usually, and the shape of a shoal alters materially with the least possible rise.

Mr. Dawson then, by the aid of diagrams, explained one or two methods for fixing points at sea, where soundings have been taken.

He then affirmed that—Another important object in marine surveying is to ascertain the direction and rate of the currents in which the tide flows' These results are usually obtained in the following manner:—At low water we proceed to the farthest point, in a boat, having provided a number of floats, made by cutting pieces of plank about 6 in. by 12 in. half through in the middle, and putting two together, so as to form a cross. We drop one or two of these in places where the current appears to run the strongest, following in our boat that which takes the lead, marking its position at intervals by fixed points, noting the time as well; thus having obtained these points, it is easy to determine the rate at which the tide runs, and in what directions. If any of the floats are stopped, or get into eddies, or if anything occurs to prevent the obtaining of a true result, we drop others; and by repeating these operations an accurate result is usually obtainable. The rate of tide current is from 1 to 5¼ miles an hour, varying very much, and is usually strongest at about half-flood and ebb.—Mr. Dawson then referred to deep sea soundings, and gave, in a condensed form, what Lieut. Maury, of the U.S. Navy, states upon the subject. He afterwards mentioned Mr. Brooks's, of the U.S. Navy, apparatus for deep sea sounding, as being the best yet invented. The working of this was clearly shown by a diagram. The authors concluded their Paper by hoping that it had been of some interest, inasmuch as there are so very few, if any, works published on the subject.

ROYAL SCOTTISH SOCIETY OF ARTS.

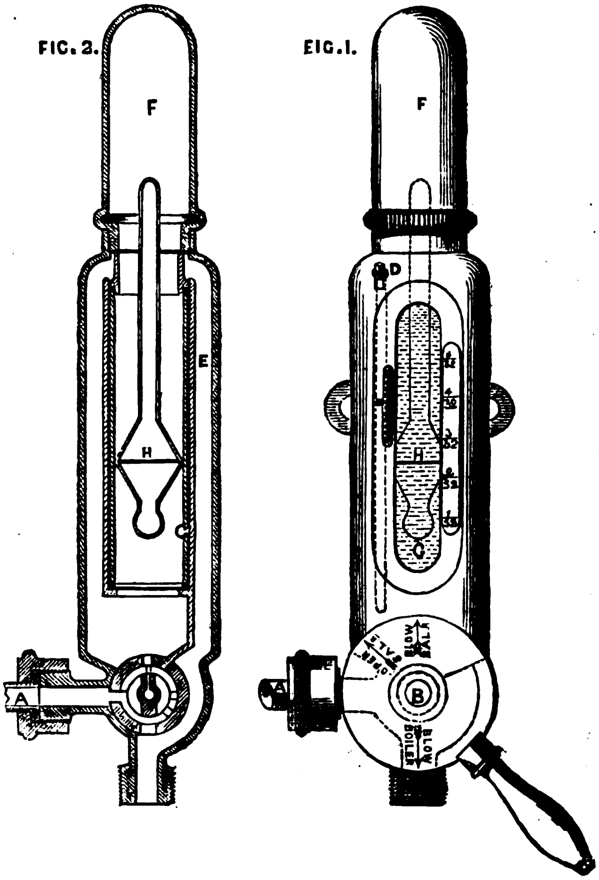
On Monday night, a meeting of this society was held in their hall, 117, George-street, Edinburgh, Dr. Stevenson Macadam, president of the society, in the chair. Mr. Edward Sang read a communication "On the Nature and Management of the Sefinet Equation for determining the Form of a Ship's Hull," which was illustrated by a model and a series of diagrams. The Paper was remitted to a committee. There was also remitted to a committee a Paper by the Rev. James Newlands Miller, "On the Effective Power transmitted from the Piston-rod to the Crank of the Steam-engine; the Work effected by the Crank; and the Lateral Strain on the Piston-rod at its Junction with the Connecting-rod." The last communication was one by Mr. Gray, engineer, Gas Works Dunfermline, giving a "Description of an Apparatus for Impregnating Gases with a Vapour of Volatile Hydrocarbon Fluids, and suitable for the purposes of Illumination." The Paper was illustrated by a model and drawings. It was remitted to a committee. Reports were read from committees on Mr. Alexander Cunningham's Paper, "On Fogs at Sea and Fog Signals on Shore," and on Mr. Heriot Currie's proposed improvement in the mode of taking in the injection water to supply marine condensing engines. The report on Mr. Currie's Paper was to the effect that the committee could not recommend the proposed improvement to the favourable consideration of the society. The report on Mr. Cunningham's Paper recommended that it should be handed for consideration to the Society's Printing Committee, as likely, if published, to prove a useful means of calling attention to an unsolved problem.

TRIAL TRIP OF AN ITALIAN ROYAL MAIL STEAMSHIP.

On Thursday last week, the "Marco Polo," a fine paddle steamer of 750 tons B.M., built by Messrs. Wm. Simons and Co., at the London Works, Renfrew, sailed down the river on her trial trip, and gave entire satisfaction to her owners, who were on board. This vessel, launched recently with all her machinery on board, is a beautiful specimen of marine architecture. She is 220 feet in length, 26 in breadth, 14 feet deep, is, as already stated, 750 tons burden, and will be propelled by a pair of oscillating vertical engines of 250-horse power, supplied with steam by four tubular boilers, fired from 12 furnaces. She is fitted with feathering float paddles, and all other improvements to secure speed, and economy of fuel in working. The arrangements for the comfort, nay luxurious ease, of passengers, are quite complete; and ample accommodation has been made for the officers and crew of the ship. The saloon, which is on deck, forming a full poop, is 50 feet long by 20 feet in breadth, with a height of 7 feet 9 inches. This apartment is decorated with all the taste and refinement and in the style of a first-class drawing-room. What may be called the walls are adorned with beautiful paintings, representing Italian places of interest, such as Sorrento, the Tiber, Pomaret, Fort-Beil-Gorod, the Sido port of Venice, the town and harbour of Bona, the Bay of Naples, Mount Etna, Bona, and Palermo, between which, in the centre of bird-eye maple panels, are emblazoned coats of arms of such towns as Siragusa, Livorno, Torino, Lucca, Messina, Catania, Ravenna, Cagliari, Milano, Genova. There is a large amount of gilding throughout the saloon, and with a judicious introduction of stained glass, mirrors, crimson velvet cushions, and lounges, a splendid rosewood piano-forte, and beautiful candelabra, the saloon presents an appearance of splendour and comfort of which few vessels can boast. Adjoining the saloon is a handsomely fitted up ambassador's room; and below the saloon is a double range of sleeping cabins, with two ladies' state rooms, all of which are well lighted and ventilated. The accommodation for second-class passengers is also excellent, there being three rooms set apart for them—in the one are sixteen berths, and in the others nine and seven respectively.

GAMBLE'S PATENT SALINOMETER.

GAMBLE'S SALINOMETER.



Of the advantages which result from the use of salinometers for ascertaining the density of the water in marine boilers, it would doubtless seem somewhat late in the day now to speak—inasmuch as they are universally recognized and admitted to be beyond dispute—salinometers in some form or other being employed in every sea-going steamer with a resulting economy in fuel and the prevention of injury to the boiler. However, amongst the different varieties of the salinometer introduced, many are open to objection—some from their complexity and liability to derangement, and others in consequence of the aim at extreme simplicity having caused them to be deficient in contrivances for protecting the engineer from injury by scalding, and the hydrometer and thermometer from breakage. From this oversight many patented contrivances possessing a certain degree of merit have entirely ceased to be used, or are only used with precautionary modifications suggested by the ingenuity of the engineer in charge. That some improvements are required by which a salinometer could be made which should be free from any of the above objections, has long been felt, and more especially has this been the case with those into whose charge such instruments are committed for use. The salinometer which we illustrate above is the invention of Mr. W. S. Gamble, for whom Mr. M. A. Soul, of Leadenhall-street, is the sole agent. A is the inlet communicating with a three-wayed cock, by which the operation of blowing out the supply-pipe and salinometer can be performed in a few seconds. B is a conical pointed screw fitted in the head of the cock plug, by which the supply of water can be regulated for keeping up the required temperature in the salinometer. C is a glass tube through which the hydrometer is seen; the density of water is here read, from a coloured glass ring around the circumference of the bulb—the scale is affixed to the outer casing of the salinometer. D is a hole for inserting the thermometer, into which a screw is fitted afterwards. E is a communication passing up between the outer and inner cylinders to the top of the instrument, by which the surplus water is carried off. F is a cover screwing on to the case, inside which the stem of the hydrometer rises; this cover entirely prevents ebullition, and forms the whole into one complete instrument, which can be attached to the boiler front if required, without any possibility of scalding persons engaged beneath.

The Prussian Minister of Commerce has authorized the construction of a railway from Dantzic to the frontier of the kingdom of Poland.

Meetings for the Week.

Mon.—*British Architects.*—Annual Meeting of Members, at 8 p.m.

Medical.—Council Meeting, at 8 p.m.

United Service Inst.—At 8.30 p.m.

Geologists' Association.—"On some Recent Shells found in Lancashire," by J. Rofe, F.G.S. "Geological Ramble on the Banks of the Medway," by Prof. Tennant, at 7 p.m.

Tues.—*Inst. Civil Engineers.*—"American Iron Bridges," by Zerah Colburn, Esq., at 8 p.m.

Wed.—*Soc. of Arts.*—"On Bread-making, with Reference to the Condition of those employed in its Manufacture," by Dr. Andrew Wynter, at 8 p.m.

Geological.—I. "On the Brick-pit at Lexden," by Rev. O. Fisher, M.A.; with a note on the *Coleoptera*, by T. V. Wollaston, Esq., F.R.S. II. "On the Original Nature of Mica-schist," by H. C. Sorby, Esq. III. "On the Fossil Corals of the West Indies. Part I.," by P. M. Duncan, M.D., at 8.30 p.m.

Thurs.—*Antiquaries.*—At 8.30 p.m.

Linnæan.—At 8 p.m.

Royal Soc.—At 8.30 p.m.

Chemical.—At 8 p.m.

Fri. — *United Service Inst.*—"The Recent Campaigns in Virginia and Maryland," by Major F. S. Taylor, at 3 p.m.

London Inst.—"On Economic Botany," by R. Bentley, Esq., at 7 p.m.

Architectural Association.—Class of Design—Choir and Chancel Screen.

Horsham, Dorking, and Leatherhead Railway.—The ceremony of cutting the first sod of this new line of railway, was performed on Saturday last, at Horsham, by Mr. Seymour Fitzgerald, M.P. By this project, in addition to numerous local advantages, a new main line will be established between London and Brighton, passing by Shoreham, Horsham, Dorking, and Leatherhead, which will be entirely distinct from the existing main line, and only a few miles longer. On this line there will be only two short tunnels, between London and Brighton—one at Dorking, of a little over 300 yards, and the other at Mickleham, of about 500 yards, the passage through each of which will only occupy the fraction of a minute. The length of the line from Horsham to Dorking is 18¼ miles.

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the Mechanics' Magazine at the rate of 6d. per line, or 5½d per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisments.

All communications should be addressed to the Editor, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

Received.—J. Y.—M. A. S.—J. J. M.—Rev. T. O. M.—O. J. R.—R. P. (your suggestion is impracticable).—H. G.—R. M. L.—F. R.—Com. T. E. S.—Messrs. L. Bros.—R. T.—J. C.

J. Y.—Our meaning was that coal is only lately being introduced for locomotives after coke had been exclusively used for so many years. The "desiderata" are simply a perforated fire-door, a fire-brick arch, and a deflecting plate, applied to the locomotive fire-box. We then gave it as an instance illustrating the difficulty of arriving at once at a simple solution of a mechanical problem, and as an illustration of the fallacy of the opinion that such questions are solved by a process of "spontaneous generation."

I. D. (Hadham).—Your proposed arrangements are simply absurd. 1. How, in the name of common sense, can you expect to prevent steam boiler explosions due to overpressure by merely separating the steam from the water? 2. Your water-valve would not work in time; and, even if this were the case, it would be a danger of itself, and the remedy would be worse than the disease.

T. L.—You had best see the "London University Calendar" for complete particulars, but the full time required for the degree of Doctor of Science at the London University is four years from the matriculation examination. You must pass two examinations in mathematics, including arithmetic and algebra, geometry, plain trigonometry, mechanical and natural philosophy, chemistry, botany, and zoology, before you can obtain the degree of Bachelor. After that, you must wait two years before you can pass for Doctor of Science. For a German Ph.D. degree, a residence at the University of a fortnight to six weeks is required; but, besides this, a candidate must be prepared with good testimonials, a thesis of some sort or other, and about £50 in money.

Correspondence.

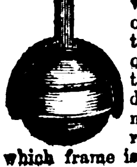
[*We do not hold ourselves responsible for the opinions of our correspondents.*]

◆

PANTAGRAPH SUPPORTING WHEELS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—I forward for insertion in the Mechanics' Magazine the following simple plan of a substitute for the supporting wheel of a pantagraph, or for any similar purpose. I was led to its contrivance on account of the annoyance experienced from the jerk, which takes place with the ordinary wheel when quick turns are to be made by the pantagraph. The drawing (full size) represents a boy's marble inclosed between two curtain rings, which are soldered to a frame, which frame is an old stretcher of an umbrella. Your readers may, of course, employ more elaborate materials, but they will find the above rough and ready ones to answer.

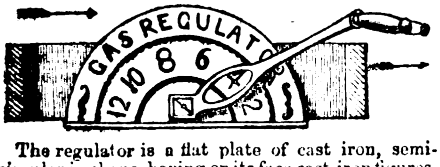


I am, Sir, yours respectfully,
N. S. Heineken.

Sidmouth, April 16, 1863.

GAS REGULATORS.

Sir,—With this I send you a sketch of a cheap gas regulator, by the use of which any person may regulate the supply of gas to the number of burners used. It consists of an ordinary 1¼ in. gas tap, the key of which has a perforation, through which the number of lights required can be seen on the regulating plate.



The regulator is a flat plate of cast iron, semicircular in shape, having on its face cast-iron figures, so arranged that when, for instance, the tap is at 6, only sufficient gas for 6 ordinary burners will be admitted into the pipes leading from the meter.

I am, Sir, yours truly,
Henry Baker.

Miscellanea.

We learn that Messrs. Gwynne and Co. have received orders from the Admiralty for the supply of the pumping engines for the new docks at Malta (their patent centrifugal pump is to be used), and of a capacity capable of discharging 25,000 tons of water in 4 hours. Messrs. Gwynne have also in hand a pair of engines with their centrifugal pumps, for the dry dock of Messrs. Palmer Bros., shipbuilders, Newcastle-on-Tyne, and to discharge 240,000 cubic feet of water in 3 hours, for the new floating dock for the Dutch Government being constructed in Holland.

The Steamer "Prince Consort."—We are gratified, says the *Aberdeen Journal*, to announce that the operations which have been for a short time carried on in connection with the wreck of this vessel at the entrance to the Harbour, were brought to a successful termination early yesterday norning, when the whole mass, engines, boilers, and hull, weighing about 600 tons, was floated from off the dangerous and rocky platform where it lay, and brought to the gridiron at Messrs Hall and Co.'s building-yard, where it now lies in perfect security. The apparatus adopted for effecting this is a patent invention of Captain Jonathan Russell, of Lloyd's, worked by the Pneumatic Ship-raising and Universal Salvage Company of London, and applied under the superintendence of Mr. Caulfield, one of their directors. The novelty of the system excited more than ordinary interest But the powerful appliances brought into use, with the active exertions of Mr. Caulfield, of Mr. Leckie, the manager for the owners, and of Captain Gauld, pilot-master, rendered this very difficult operation a complete success. The caissons used on the occasion were manufactured by C. Macintosh and Co., Cambridge-street, Manchester, and 3, Cannon-street West, London.

Iron-clads.—The presence before Charleston, says the *New York Times*, of three distinct types of iron-clads, represented by the "Monitors," the "Keokuk," and the "Ironsides," affords an interesting means of comparing the relative merits of the different models. The test is, however, hardly a fair one, as some of the vessels were much more exposed to fire than others. It would have been interesting, for example, to have seen how the "Ironsides" would have behaved under the amount of fire received by the "Keokuk," and under the same range at which she was placed. This would also have afforded the means of testing the relative strength of continuous and of laminated armour—the plating of the "Ironsides" being one single 4½ in. mass of wrought iron, and that of the "Monitors" in series of 1 in. plates. So far as we may be justified in drawing an induction from a limited range of facts, the advantage would seem to incline to the continuous thick plating. The exposed overhanging port-covers, employed both on the "Ironsides" and "Keokuk," and which in the case of both ships were in several instances shot away, appears to be an undeniable weakness. The riddling of the armour of the "Keokuk's" turrets, which consists of 5¾ in. of iron, presents a striking proof of the penetrating power of the improved modern projectiles; and the effect produced by the square-headed and steel-pointed shot would seem to justify all that has been anticipated of their power. The "Nahant" received several bad fractures of the deck and sides, below and above the water line. The most fatal blow, however, was given by a heavy rifled shot, which struck the pilot-house, and dislodged several of the bolts, one of which, driven violently inwards, wounded all of the three inmates of the pilot-house. The most extraordinary shot the "Passaic" received was from a large 10-in. rifled projectile, which struck the top of the turret, scooping out a huge portion of the iron, breaking all of the eleven plates of an inch thickness each, and spending its force on the pilot-house (which is placed on the top of the turret), in which it made a crater 3 in. deep, and producing such a shock on the pilot-house as to start its top and raise it up three inches! Had not the force of the impact been broken on the turret, there can be little doubt that this shot would have gone clean through the pilot-house. Another shot hit the turret, forcing the place struck inwards, and producing a big swell on the interior. The same shock disabled the carriage of the 11-in. gun, while portions of the interior iron casing fell down, and, lodging in the groove of the turret, stopped its revolution. The "Nantucket," besides receiving a number of wounds, had her turret so jarred that the cover of the port could not be opened, and, consequently, the 15-in. gun could not be used. These three, the "Passaic," "Nahant," and "Nantucket," are all of the "Monitor" type.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 2739.
Boilers and Furnaces, 2713.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 2683, 2702, 2704, 2737.
Ships and Boats, including their fittings, 2693, 2714, 2719, 2722, 2727, 2735, 2740.
Cultivation of the Soil, including agricultural implements and machines, 2699, 2712.
Food and Beverages, including apparatus for preparing food for men and animals, 2686, 2701, 2706.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 2680, 2681, 2691, 2694, 2715, 2717, 2724, 2728.
Buildings and Building Materials, 2695, 2696, 2725, 2738.
Lighting, Heating, and Ventilating, 2684, 2688, 2690, 2711, 2741.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 2685, 2689, 2697, 2705, 2709, 2716, 2721, 2731.
Metals, including apparatus for their manufacture, 2708, 2730.
Chemistry and Photography, 2698, 2718, 2729.
Electrical Apparatus, 2734.
Warfare, 2710, 2723.
Letter-Press Printing, 2733, 2736.
Miscellaneous, 2682, 2687, 2692, 2700, 2703, 2707, 2720, 2726, 2732.

2680. A. Barclay. *Improvements in printing textile materials and fabrics, and in machinery therefor.* Dated October 4, 1862.

This invention comprises improvements more particularly designed for printing yarns or warps to be afterwards woven into piece goods, but also in part applicable for printing woven fabrics. In one modification of machinery or apparatus for carrying the invention into practical effect, the yarns or warps having been first beamed or wound in a regular way upon one or more beams or rollers, and such beam or beams having been placed in supports provided for them in the machine, are drawn thence and made to pass round more or less of the circumference of what may be termed the impression cylinder. In passing round such impression cylinder, the warps receive the desired impressions from one or more printing rollers, in one or more colours, the impressions being, by preference, produced by relief surfaces, and the printing rollers being disposed with their colour supplying details according to any suitable arrangement such as is at present in use for printing woven fabrics. The printing roller may be supplied with colour either by a sieve or small endless blanket passed round two rollers, the lower one dipping down into the colour trough; or it may be supplied by means of a series of two or more elastic surface rollers, the lowest revolving in the colour trough, and imparting its colour to the next in contact with it, and this one again either to a third, or directly to the printing roller. There is interposed between the warps and the surface of the impression cylinder an endless blanket of glazed or varnished cloth to form a suitable back surface behind the warps, and which receives the portions of colour which pass through or between the warps. This endless cloth or blanket is of sufficient length to be passed over guide rollers to a little distance from the impression cylinder, and it is made to pass through washing apparatus, which may consist of a trough of water with frictional appliances contrived to act on the cloth or blanket. From the washing apparatus the cloth or blanket passes between squeezing rollers to remove the moisture, and, if necessary, in contact with a rubbing surface when it is rendered fit to re-enter upon the impression drum without any possibility of spoiling the warps with which it comes in contact. The printed warps are made to leave the impression cylinder, by preference, in a horizontal direction, and are immediately subjected to the drying action of heat. *Patent completed.*

2681. W. E. Gedge. *Improved means or apparatus by the use of which pierced or perforated cocoons may be spun.* (A communication.) Dated October 4, 1862.

This invention is not described apart from the drawings. *Patent comptcled.*

2682. S. Amphlet. *An improvement or improvements in ornamenting surfaces of wood.* Dated October 4, 1862.

This invention consists in ornamenting surfaces of wood by mounting directly thereon photographs of objects from which the background has been cut away, the surface of the wood on which the said photographs are mounted constituting the background to the said photographs. *Patent abandoned.*

2683. J. E. Billups. *Fixed points for railways.* Dated October 4, 1862.

This invention consists in dispensing with the moveable tongues and switches, and substituting in place thereof fixed points, so arranged that they will always keep the carriages, engine, or otherwise within a proper track. *Patent completed.*

2684. J. M. Cabirol. *A submarine lamp.* Dated October 4, 1862.

The main features of this invention consist in condensing or taking up the heat of the current of smoke and air issuing from the lamp, thus cooling it to such a degree that it cannot burn or injure the flexible tubing which is employed in this lamp. The patentee attains this object by causing the said current to pass down outside of the lamp into a coil, where it is cooled by contact. Another feature consists in drawing off the said current, through a pipe, terminating the said coil by means of an air-pump, thus creating a partial vacuum, which causes the external air to rush in through another pipe into a distributing passage provided for that purpose near the bottom of the lamp. This submarine lamp is made up, besides the piping mentioned, of two hollow spheres of crystal, the lower and larger one containing a Carcel moderator or other lamp, and the upper one, which communicates by the lamp funnel only with the lower sphere, receiving the products of combustion, which are drawn off into the refrigerating coil, as before described. *Patent abandoned.*

2685. F. PARKINSON. *Improvements in ladies' shawls and cloaks.* Dated October 4, 1862.

This invention consists in forming or producing ladies' shawls and cloaks of separate materials arranged and secured with their inner surfaces together, admitting of the reverse sides being folded over or outwards, as required, the ends being left unsecured for that purpose, and edgings or trimmings corresponding to the same employed in like manner. *Patent abandoned.*

2686. F. WATKINS. *Improvements in apparatus for milking cows.* Dated October 4, 1862.

For the purposes of this invention four elastic flexible teat cups, made of vulcanized india rubber, are used to receive the four teats of a cow. The lower ends of these teat cups are fixed to a hollow ring or vessel. In the centre of this hollow ring or vessel a chamber is formed, over which a flexible dished diaphragm is fixed, the centre part of which is arranged to be moved up and down by a lever handle, the end of which is attached to a disc or plate fixed in the centre of the flexible diaphragm. At the bottom of the hollow ring or vessel is a valve which opens outwards, and below this valve is a spout into which the milk is received as it descends from the hollow chamber or ring to which the flexible elastic teat cups are attached. The hollow ring or vessel and apparatus is supported on a suitable stand, so as readily to admit of the teat cups being brought into position under a cow to receive the four teats. When the flexible diaphragm is moved in one direction, the pressure of air within the hollow ring or chamber is reduced, and the milk is thus caused to flow from all the teats; when the flexible diaphragm is moved in the opposite direction, the milk received into the hollow vessel is forced out therefrom through the valve, the milk ceasing to flow from the teats during the time that milk is flowing from the hollow vessel. The movement of the flexible diaphragm again in the direction first mentioned will again reduce the pressure of air in the hollow vessel, when the milk will again flow into the hollow vessel, and so on, the milk alternately flowing from the teats and then from the outlet spout of the vessel. *Patent completed.*

2687. F. E. BLATSFIEL. *Improvements in diving apparatus, and apparatus to be used for working in deep water.* (A communication.) Dated October 4, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2688. W. CLARK. *Improvements in the means of preserving goods from fire, and in apparatus for the same.* (A communication.) Dated October 4, 1862.

In carrying out this invention, the inventor places the merchandize or combustible materials on small trucks placed on inclined planes in proximity to basins or channels filled with water. When left to themselves, these trucks carry the merchandize with which they are charged into the water, in order to cover them with water, being simply retained in position by means of detents or stops. When a fire breaks out, all the catches are disconnected, which allows the trucks to roll of themselves into the water channels, together with the merchanize. These improvements are especially applicable to stores of wood, tar, or cordage in marine arsenals. *Patent abandoned.*

2689. G. WHICKER and L. BLAISE. *Improvements in skates, and in the method of securing or fastening the same.* Dated October 4, 1862.

Provisional protection has not been granted for this invention.

2690. F. JOHNSON. *Improvements in domestic fire-escapes, and in receptacles for the same.* Dated October 4, 1862.

These domestic fire-escapes are capable of being folded into a small space when not in use, and enclosed in a folding receptacle, the sides and ends of which fall back, and lie flat on the floor on the lid being raised, thus instantly removing all obstruction, and allowing the folding escape to run out through any contiguous opening perfectly free. The folding case or cover is mounted upon castors or runners, and is fitted with handles at the sides, so that it can e easily run or carrird from one room to another; and for ontaining an escape and appliances complete for a five-torey building, only occupies a space of about 30 in. in ength by about 20 in. in width and height. For facilitating the escape of children or invalids, in addition to the folding ladder, there is an invalid bag, the back and floor of which are made to fold, and, when opened out for use, be rigid; the back is attached to the ladder so as to run up and down upon it by means of a rope containing a wire strand, and of sufficient strength to support two adults. This rope is attached to the bag by a spring hook, and the bag secured upon the ladder by projecting flanges at each side, the two ends of which flanges are connected by a chain which passes at the back of the ladder. At each end of the ladder the patentee fits a length of tested block chain or wire rope terminating with a ring or spring snatch-hook; the bottom chain is intended for securing the ladder at the level of the ground at a suitable distance from the building, or at any required angle vertically, while the chain at the top of the ladder is intended for securing it to the wall of the room or apartment, between which and the ground, or between which and any other floor, the establishment of a communication is required. The wall hook, which forms part of the apparatus, consists of a bolt, at one end of which a spring hook is formed, the other end being screwed and fitted with a plate and tightening nut. These wall hooks it is proposed to fix in the wall, inside the building, immediately under the windows or openings of the upper floors. *Patent completed.*

2691. W. TAYLOR and S. BUCKLEY. *Improvements in machinery for preparing cotton and other fibrous materials.* Dated October 4, 1862.

This invention is applicable, first, to openers, blowers, and other machines of the like nature, in which drums or beaters are employed to act upon the fibrous materials. In performing the invention, the patentees make use of a hollow drum or cylinder, provided with slots for toothed or plain blades of steel or other metal to enter between. These blades are attached to bosses loose on a shaft, which shaft is eccentric to and connected with the hollow drum or cylinder, so that, when rotatry motion is communicated to the shaft, the drum revolves also, and the blades are caused to project beyond and enter within the slots. By this arrangement, the fibres presented by feeding rollers or otherwise to the drums are acted upon by the toothed or other blades, and effectually opened and cleaned. Secondly, a similar arrangement of parts is also applicable to carding engines for stripping the fleece of fibres from the surface of the doffer. Thirdly, in order to keep the apparatus clean, they apply a rotary clearer or an endless band to the surface. The clearer is applicable to other apparatus for stripping the doffer. *Patent completed.*

2692. R. PAGE. *Improvements in stables and stabling, applicable in part to kennels and to the floors of fish-houses.* Dated October 6, 1862.

Here the patentee makes waterproof or non-absorbent floors for stables or kennels (and fish-houses) by the use of an artificial stone or composition, consisting of the substance known as Portland cement, combined with fine sand and fine shingle, also finely-powdered clinkers from furnaces, which have been comminuted by grinding or pounding. *Patent completed.*

2693. T. KEECH. *Improvements in floating batteries.* (A communication.) Dated October 6, 1862.

This invention consists in the employment in combination with any kind of ships' hull or body of a floating turret, so arranged as to float in water, or any other suitable fluid contained within the ships' hull, or in a compartment formed therein, and be readily rotated by machinery in the turrets. The invention also consists in forming a communication between the inside of the ship and the inside of the turret by a suitable passage way through hollow frames which sustain the central shaft and through the said shaft, as described. And the invention further consists in a novel arrangement of the guns on curved railways. *Patent completed.*

2694. J. and W. BRADBURY. *Certain improvements in carding engines.* Dated October 6, 1862.

This invention relates to that portion of the carding engine used for carding cotton or other fibrous substances known as the doffer, and consists in the peculiar arrangement and combination of two grooved cams with double bell crank levers for giving motion to the doffing comb. The doffing comb is secured at its extremities to the levers, the grooved cams acting upon the extremity of the vertical part of the levers, and the third extremity opposite to the doffing comb serving as a balance. The lever is made adjustable (so as to set the comb) in the middle of its horizontal length; that is, immediately beneath the vertical part of the lever. The chief feature in the invention is the use of grooved cams having anti-friction bowls running in them, and combined with the double bell crank levers, in contradistinction to the use of face cams or eccentrics, and connecting rods to connect the vibrating levers with them. The invention effects a considerable improvement upon the doffing motion so constructed. *Patent completed.*

2695. D. LOWE. *Improvement in the manufacture of door bolts and latches.* Dated October 6, 1862.

This invention consists in the methods hereinafter described in making the barrels and plates of the said bolts. In making the barrels and plates, the patentee takes a piece of sheet iron of the length of the plates, and by dies, stamps, or presses, he raises along the middle of the sheet an arch which constitutes the barrel in which the bolt slides. Portions of the said arch are at intervals bent in opposite directions, and constitute bands which hold the bolt in the arch or barrel. A narrow band at the end of the barrel is less depressed than the others, and constitutes the top of the bolt. Or, in place of a continuous barrel, he employs one, two, or more separate arched bands in which the bolt slides, and he fixes the said arched band or bands to the plate by turning the edges of the plate over the ends of the said arched band or bands. The improvement in the manufacture of latches consists in the method hereinafter described of making the plates of the latches, and in making and working the lever or latch. He makes the plates of the latches by dies and stamps or presses in a way similar to that by which he makes the barrels and plates of bolts; that is, he cuts and raises from a sheet of iron the strap or guard under which the lever or latch works, and also perforates the plate for the axis of the latch. Or he makes the said strap or guard from a separate piece of sheet iron, and fixes it to the plate by turning its ends over the edges of the plates. When the latch turns upon a centre in the plate, he makes a projecting hollow axis on the end of the latch by means of a press or stamp, and causes the latch to be held down by means of a coiled spring. When the latch turns upon a centre in the strap or guard, he causes the latch to be held down by means of a spring coiled around its axis. *Patent completed.*

2696. S. HOLLAND. *Improvements in machinery for the manufacture of bricks, drain, sanitary, and other pipes, tiles, quarries, and other articles of like manufacture, made from clay, marl, and other plastic substances.* Dated October 6, 1862.

This invention consists, essentially, in forcing the column of clay or other plastic substance through dies for the manufacture of bricks, pipes, tiles, and other articles of like manufacture, by hydraulic pressure. *Patent completed.*

2697. W. CLARK. *Improvements in articles of clothing.* (A communication.) Dated October 6, 1862.

This invention consists, essentially, in applying an elastic gusset to trousers, drawers, and other similar articles of clothing. *Patent abandoned.*

2698. J. NEWNAM. *Improvements in apparatus for crystallizing and for evaporating.* Dated October 6, 1862.

This invention was described and illustrated at page 308 of the present volume of this journal. *Patent completed.*

2699. T. BEARDS. *Improvements in machinery for cultivating land.* Dated October 6, 1862.

This invention consists essentially in combining with a rigid running frame two rising and falling end frames carrying ploughs, grubbers, and cultivators, by which the several operations of ploughing, grubbing, and cultivating may be separately performed. *Patent completed.*

2700. S. F. COX. *Improvements in washing and tanning hides and skins.* Dated October 6, 1862.

The patentee claims so suspending or fastening hides or skins within a rotating frame, that they shall alternately roll or fold up, and again straighten, whilst immersed or partially immersed in fluid. *Patent completed.*

2701. A. V. NEWTON. *Improved apparatus for drying grain.* (A communication.) Dated October 6, 1862.

The documents relating to this invention cannot at present be seen, an extension of time for filing the final specification having been petitioned for.

2702. C. CHINNOCK. *Improvements in the construction of axle-boxes.* Dated October 6, 1862.

The chief object of this invention is to remove or neutralize the friction that is now commonly created between the axles and axle-boxes of carriages, caused by the lateral pressure of the wheels against the collars or shoulders of the axle. This the patentee effects by coupling together the axle and axle-box, by means of antifriction balls, in such a manner that, where a cap is used for closing the axle-box, the connection may be readily made and also maintained on the temporary removal or displacement of the cap without risk of the antifriction balls dropping out of place. By a modified arrangement, he is enabled to provide against the displacement of the balls on the removal of the box itself from the axle. *Patent completed.*

2703. J. HEAP. *Improvements in screw stocks and dies.* Dated October 7, 1862.

This invention consists in making screw stocks of one piece, having dies, one or both furnished with a tail screw on which is a nut fitting in a concave recess in the screw stock, as hereinafter described. The dies are portions of cylinders, or of other suitable shape, and have V-grooves fitting on similar projections in the screw stock, which is made in the form of a fish belly at the centre to combine strength with lightness, and to reduce labour in constructing. The centre portion of the slot in the screw stock is enlarged to allow the dies to be put in their places and removed. The dies may be made of cylindrical pieces of steel, which are screwed into the screw stock; each die may be provided with three cutting recesses for securing bolts or other articles of different diameters. *Patent completed.*

2704. J. SMITH. *An improved screw linchpin for carriages and agricultural implements.* Dated October 7, 1862.

This invention consists in making an aperture in the linchpin large enough to receive a screw; a hole is then drilled from the end of the arm up to the linchpin, and the screw is then applied and fixed in the aperture of the linchpin. This arrangement prevents the possibility of the linchpin falling out. *Patent abandoned.*

2705. W. ASTON. *Certain improvements in the manufacture of buttons for ladies and gentlemen's wear.* Dated October 7, 1862.

This invention consists—1, In adapting revolving beds or tables to the process of fixing together and closing the parts necessary in making covered buttons, such beds being divided, turned, and simultaneously put in motion by a suitable mechanical arrangement. 2, The improvements consist in the application to buttons covered on the edge and faced with suitable woven fabrics of a circular or other shaped metal front, smaller than the general diameter of the button, so as to show a covered edge around the metal part. *Patent abandoned.*

2706. J. OXLEY. *Improvements in apparatus for expressing and separating beer from yeast or barm.* Dated October 7, 1862.

This invention consists in the combination of perforated plates or boards or wire screens with cells or bags of cloth, into which the semifluid substances are forced by means of a pump, the pressure applied to the same being sufficient to express the liquid through the cells or bags, whence it passes through the perforations in the plates or boards, or the spaces between the wires of the screens, into the receptacle required. *Patent abandoned.*

2707. F. RAHLES. *An improved safety envelope.* Dated October 7, 1862.

This envelope the inventor can make to resemble—in so far as relates to the appearance of the back thereof—the ordinary envelope, though he does not open the envelope by moving a flap or flaps at the back as usual. The flaps at the back have a part of the envelope as large as the front of the envelope underneath them, so that, when these flaps are removed, the inside of the envelope has still to be got at by opening this under part. There is a flap at one of the ends of the envelope in front thereof (by preference the right hand end), which flap he prefers to make as perforated net work, or open work, or notched out at the edge, and he applies to the said flap the gum or adhesive compound for fastening the envelope. To the edge of the other part of the envelope to which the said flap is to be fastened, he can apply, if necessary, a coloured composition, or a stripe of any kind, which shall (if desired), upon the flap having been once fastened thereto, and after wards removed, show, by discolouration or otherwise, that violation has taken place. Around two of the edges, and the end opposite the opening flap, is a small cord, the two ends of which are left slightly protruding close to the opening flap, by pulling which cords the envelope will be cut open, when it has to be opened by the recipient thereof in the proper way. *Patent abandoned.*

2708. A. Forbes. *Improvements in connecting together parts of vessels formed of tin plate, and in the means or apparatus employed therein.* Dated October 7, 1862.

The object of these improvements is to facilitate the connecting together of the top and bottom plates or covers to the bodies of cans for holding preserved provisions, as also of similar parts of vessels formed of tin plate for other uses. The patentee forms the outer end or edge of the body of the can or other vessel, or that part to receive a cover, somewhat enlarged, or of a socket form and bell-mouthed, by swaying or otherwise, and he forms the top or bottom (as the case may be) with a turned-up edge, somewhat bell-shaped or inclining outwards, so that its outer edge, when pressed into the socket of the body, may press close to the inside thereof, and leave a groove or channel above for solder. The solder he applies in or over the channel in a ring or other form, adapted to the shape of the vessel, adding resin or other suitable flux to facilitate union of the parts on the application of heat thereto. And then, in place of a soldering iron, he applies the heat to the whole of such surface by means of a heated metal ring or frame, with a groove therein adapted to one part of it, embracing the whole of the side surface, and the other the top edge of the parts to be connected. And to avoid interfering with the soldering already effected of the parts of the body near the top or bottom by the heat of such ring or frame, he cuts a notch or groove in the ring or frame at such part, or he applies over such already soldered part a small piece of paper. *Patent completed.*

2709. J. D. and A. P. Welch. *Improvements in machinery for blocking and pressing hats and bonnets.* Dated October 7, 1862.

In carrying out this invention, the inventors propose to mount on four vertical iron or wooden standards, an iron table, which may be formed hollow, in order to admit of its being heated by steam, hot water, or other medium, if desired. The elevation of the standards is to be continued above the level of the table, for the purpose of serving as guides, within which a dome or hemisphere of iron or other metal is adjusted. This dome is provided at its periphery with four equidistant slots or grooves, which take into the edges of the guides, whereby the dome is retained in a horizontal position or parallel. The lower part of the dome is furnished with a strong diaphragm or disc of india rubber, vulcanized or otherwise, secured in a water-tight or air-tight manner around the entire internal edge or circumference thereof, and the top of the dome receives a tube or pipe, which may be bolted or secured therein, and by which means hot or cold water or air, or other fluid, may be forced into the dome by means of a pump, so as to apply hot or cold hydraulic, pneumatic, or other pressure to the elastic diaphragm. Underneath the dome and diaphragm, and upon the surface of the table, a block or form, either of metal, cement, or wood, of the desired shape or pattern, according to the hat or bonnet to be pressed or blocked, is placed, and, the hat or bonnet being placed thereon, the dome is allowed to slide down between the guides until the diaphragm comes well in contact and encloses the article to be blocked, after which the dome is to be held down by means of clamping screws or other like fastenings, and the hydraulic, pneumatic, or other pressure, is then to be applied from the pump, whereby the elastic diaphragm will be extended, stretched, or forced down on to the outer surface of the hat or bonnet upon the block, and so give it the requisite pressure and shape. *Patent abandoned.*

2710. H. D. P. Cunningham. *Improvements in working the guns and in performing other necessary work on board ships, and in apparatus employed therein.* Dated October 7, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2711. J. K. Hampshire. *Improvements in machinery or apparatus for washing coal, coal slack, and other mineral substances, and in separating foreign particles therefrom.* Dated October 7, 1862.

This invention consists—1, in the application of a pair of toothed rollers for reducing the coal or other mineral substances to be operated on to a uniform size, as nearly as may be, before being introduced into the washing apparatus, which facilitates the washing operation, and the separation of the foreign, extraneous, or refuse matter, from the coal or matters being washed. 2, in the application of an oscillating plate or surface for the agitation of the water to produce the washing operation; 3, in the application of a series of metal grate bars, for the support of the materials being washed, so arranged as to permit the water to act with great force on the material being washed, and so as to admit of, and provide for, the escape thereof after a sufficient treatment in the washing or purifying chamber; 4, in the arrangement for the removal or passing away of the impurities separated from the coal or other minerals being washed. In washing coals and other minerals which are operated on in large quantities, the patentee provides suitable rails or ways and trucks to bring the minerals to the machine, at such an elevation that the materials may be allowed to descend and pass through the several operations, and then be received in trucks placed on rails or ways at a lower and suitable elevation, and be conveyed away to the heap or other store or depository. *Patent completed.*

2712. J. and M. A. Beale. *Improvements in the preparation or manufacture of manure.* Dated October 7, 1862.

This invention consists in manufacturing manure from night soil, lime, soot, common salt, and dregs of asafœtida combined in certain specified proportions. *Patent completed.*

2713. A. V. Newton. *Improvements in the construction of condensers or coolers.* (A communication.) Dated October 7, 1862.

This invention consists—1, in forming a surface condenser or cooler by placing on the outside of the submerged surface of the steamer one or more thin and flat passages, with parallel sides, containing the steam to be condensed or water to be cooled, a lamina of the water in which the vessel floats being interposed between the passages. By this means a form of condenser or coolor is obtained that will offer but little obstruction to the passage of the steamer through the water. The second part of the improvement consists in forming a surface condenser or cooler by placing on the outside of the submerged surface of the steamer a system of tubes with headers, elbows, and return bends, arranged one behind the other, so as to cause little obstruction to the passage of the steamer through the water, and at the same time to allow sufficient water to flow around the tubes to condense the steam or cool the injection water. The third part of the improvement consists in placing a guard around the condensers or coolers, so that they may not be injured by striking against any object. The fourth part of the improvement consists in so arranging a surface condenser that condenses the steam of a steamer, or a cooler that cools the injection water, that they may be disconnected from the engine, and used for the purpose of distilling fresh water from the sea water, and also that they may be readily cleaned. *Patent completed.*

2714. C. F. Terry. *Improvements in machinery for propelling vessels.* Dated October 8, 1862.

This invention consists in the combination of water cylinders and pistons, or a revolving screw, driven by a suitable engine or engines, with water channels leading from the cylinders, or the tube containing the screw to channels at the lower part of the vessel, parallel with the keel, and valves or taps for opening the communication between the water cylinders or the tube containing the screw and the last-mentioned channels for propelling forwards or backwards respectively, such valves or taps being under ready control by means of suitable mechanism for working them as required. The water cylinders or the tube and screw are fixed in or about the centre of the length of the vessel, on each side of the keel, with the valves for admitting the water at such parts of the cylinders, or in such positions with relation to the said tube, as will cause the water driven forwards by the action of the pistons, or of the screw, to pass along the channels leading respectively to the stem or stern of the vessel by the opening of their respective taps or valves. By this arrangement of the parts, the motion of the vessel can be regulated by means of the mechanism for opening and closing the said taps or valves. There are also valves for closing the channels against the admission of water when it is intended to dispense with the use of the propelling machinery above described. *Patent completed.*

2715. D. Nickols. *Improvements in machinery or apparatus for measuring and registering lace and other similar articles.* Dated October 8, 1862.

This invention is carried out as follows:—On a frame of any suitable metal or material, the inventor arranges the necessary rollers or bars, over and under which the lace or article to be measured and registered passes, the diameter of the middle roller being regulated so as to give the measurement required. On the end of the said middle roller is fixed a worm which works into a pinion on the end of a shaft, on which shaft are placed a number of toothed wheels, varying in diameter so as to form a toothed cone. Over the said cone is placed another shaft, with a loose toothed wheel working into the said cone, which can be placed at such a position as to work on any desired part of the cone to measure and register the distance or length required, which is ascertained by a graduated scale fixed on the framework near the said moveable wheel. At the other end of the said shaft is fixed a lever, with a weight or hammer at the other end of it, which lever passes the frame transversely, and is caused to rise and fall at the time the required measurement is made; and on the said transverse lever is placed a marker, which, as it descends, will pass through the material, and, by descending into a small reservoir of colouring matter, will mark the material as it ascends; or, instead of the said marker, a simple marker without colouring matter may be used. *Patent abandoned.*

2716. W. C. Burden. *Improvements in mechanism for giving the pitch or tone required in tuning musical instruments, and also the key note of vocal music.* Dated October 8, 1862.

This mechanism is designed for the purpose of enabling any person to tune musical instruments without the necessity of laying what are termed the bearings, thereby simplifying the operation, and lessening the time necessary for performing it. By this invention also the key note of any vocal music can be obtained. The inventor constructs a framework or box of suitable size and dimensions, of wood or other material, in which he places an opening in any suitable place or position, over which he stretches leather or other flexible material, so as entirely to close the said opening. In the interior of this framework or box he fixes vibrators, and on the exterior, and immediately over these vibrators, are valves or keys sliding in grooves, for the purpose of producing the tones and half-tones of the chromatic scale. A small aperture is made in the framework or box in which is inserted a mouth-piece or tube made of flexible or other material. When wind is forced into the interior of the framework or box through the mouth-piece or tube, and the valve or key of the tone or note required to be produced having previously been opened, the vibrators will produce the tone or note desired. *Patent abandoned.*

2717. T. Ratcliffe. *Certain improvements in looms for weaving.* Dated October 8, 1862.

This invention relates to such looms as are employed for weaving lenos or other similar fabrics, and consists—1, In an arrangement of apparatus for effecting certain movements of the healds. In weaving leno two or more sets of healds are required, one behind the other; and the invention consists in the employment and use of one pulley above and below the healds, and attached thereto, and so arranged that, when the front healds are raised the back healds are lowered in a line with the ways, which is effected by suspending the cone pulleys of the back healds from the pulleys of the back by means of straps, so that as the strap coils and uncoils upon the pulleys, the healds will be raised or lowered. By this means the springs to draw down the healds, as hitherto employed, are dispensed with, except the one attached to the loose heald, which is worked by the middle heald by attaching them together with a cord. A second part of the invention consists in a simple arrangement of levers actuated by a cam on the tappet shaft, to regulate the lifting off of the warp, the cam effecting the temporary yielding of the warp. *Patent completed.*

2718. P. Clavel. *Improvements in the treatment of violet colours derived from coal-tar oils.* Dated October 8, 1862.

This invention consists in an improved mode of treating the violet colours derived from coal-tar oils with a view to render them soluble in water. Over the violet matter to be treated, placed in a suitable vessel, is poured in small quantities at a time a sufficiency of cold fuming sulphuric acid of Nordhausen to effect the solution, the mass being constantly stirred. After being left to repose for about half an hour to complete the saturation, the solution thus formed is poured carefully into a vessel of enamelled iron, or other like suitable resisting material, previously charged with water, heated to from 160 to 212 deg. Fah. The whole is then exposed for a few minutes to the action of a current of steam, after which it is left to cool. The precipitation of the violet colour is then effected by the addition of chloride of sodium, or an earthy alkali, after which the mass is again heated by a current of steam, and maintained in ebullition for about half an hour. During this process the whole of the colouring matter is thrown down, and being collected on a filter is washed with cold water, until all traces of acid or alkali have disappeared. The product thus obtained is thoroughly soluble in hot water, and may be employed in the ordinary way for dyeing or printing purposes. *Patent abandoned.*

2719. J. R. Harris. *Improvements in propelling vessels.* Dated October 8, 1862.

This invention relates to giving motion to vessels by means of propellers enclosed within the body of the vessel, except at the parts of such propellers for the time acting on the water for the purpose of propulsion. The inventor forms the propellers with radial or other suitably formed floats or boards, and enclosed sides, so that the space between the adjoining floats or boards may form chambers, open only at the periphery for action upon the water, and he encloses these propellers, except where they act directly upon the water, within boxes or compartments formed for them in the hull of the vessel. By these means only the part of the propeller for the time acting projects from the vessel, and at the same time the back action of the water is avoided. *Patent abandoned.*

2720. M. A. F. Mennons. *Improvements in self-inking hand stamps.* (A communication.) Dated October 8, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2721. H. Dullens. *An improved runner or fastening for umbrellas, parasols, sunshades, and other like articles.* Dated October 9, 1862.

This improved runner is formed with a rotating collar or ring, grooved and notched to receive the stretchers. By the introduction of this rotating collar upon the runner the latter can be turned to any required position upon the stick, without twisting the frame, and thereby a simple fastening, consisting of a small pin, stud, or screw, can be substituted for the old spring catch at the top and bottom of the range of the runner, or the space it travels upon the stick when opening and closing the frame. In the old plan a long deep groove had to be cut in the stick, thereby materially weakening it at both extremities of the runner's path. This is entirely dispensed with by the improvement here described. At each end of the improved rotating runner the inventor forms a swell or enlargement of the tube, with a number of notches or openings. When the frame is open or closed, the pin, stud, or screw in the stick at the top or bottom, as the case may be, passes into the swell or enlargement at the top or bottom of the runner through one of the openings, and then a partial turn of the runner secures it in the required position. *Patent abandoned.*

2722. J. Maurice. *Improvements in steering ships or vessels, and in the apparatus to be employed for that purpose.* Dated October 9, 1862.

This invention consists in substituting for the ordinary rudder, or as an auxiliary thereto, a sliding, traversing, vibrating or partially rotating surface of metal or wood, mounted or fitted so as to work within a sheath or case, and capable of being projected into the water from the ship's sides, port or starboard, according to the required change of the ship's course. *Patent abandoned.*

2723. W. Bush. *Improvements in cannon and small arms.* Dated October 9, 1862.

This invention is designed chiefly for guns for ships and batteries, but it applies to all other guns, large and small. It consists in forming the gun in two parts—one the barrel for containing the projectile, the other the breech and chamber for containing the powder; in uniting the two parts by means of a screw or screws, as hereafter explained; and in connecting the breech and chamber to a slide, in such manner that when the breech is disengaged from the barrel, it can be turned down, as upon a hinge, for the purpose of charging the barrel and chamber. The inventor forms, say, the male screw on the rear of the barrel, and the female screw on the inner and fore end of the breech chamber; he cuts away or forms channels in both male and female screws, to allow of the chamber being slidden along the rear end of the barrel, when, by a partial turn of the chamber, the two parts become locked by the engagement of the screws. He grinds the rear end of the barrel and the seat for it in the chamber, and, if necessary, uses a washer to keep the parts gas tight. In some cases he screws a steel tube into the rear of the barrel. *Patent completed.*

2724. C. N. Wilson. *Improvements in rag-machines.* Dated October 9, 1862.

This invention consists in giving to the cylinder or swift, or to the feedr ollers of rag-machines, reciprocating motion, in addition to the usual rotary motion, thereby producing lateral as well as direct action upon the rags, fabrics, or fibrous substances acted upon. *Patent abandoned.*

2725. J. H. Johnson. *Improvements in polishing precious and other hard stones, and in the machinery or apparatus employed therein.* (A communication.) Dated October 9, 1862.

This invention relates to an improved mode or method of polishing pieces of rock, containing jasper, pure jasper, and other precious and hard stones, and consists, essentially, in the polishing of such substances without the intervention of polishing powders or substances of any kind between the wheel and the stone under treatment. The polishing wheel is composed of fine grit stone, and the dust powered is produced from the stone by a ventilator or brush slightly wetted being occasionally applied to the wheel for the purpose of preventing it from over-heating. *Patent abandoned.*

2726. J. H. Johnson. *Improvements in the manufacture of paints or pigments.* (A communication.) Dated October 9, 1862.

The patentee claims—1, The manufacture of paints or pigments, having a base of powdered galvanic copper, or of powdered copper which has been in a state of fusion. 2, The manufacture of paints or pigments having a base of benzole mixed with resinous, gummy, asphaltic, or bituminous matters, before being incorporated with the oils and metallic oxides, carbonates, or sulphides, such paint possessing all the varieties of tone and colour before its admixture with the before-mentioned metallic oxides, carbonates, or sulphides. 3, The application of these paints or pigments to all surfaces heretofore covered or coated with paint. *Patent completed.*

2727. R. Hammond. *Improvements in armour for ships of war.* Dated October 9, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

2728. A. V. Newton. *Improved machinery for breaking and cleaning flax, hemp, and other like fibrous substances.* (A communication). Dated October 9, 1862.

This invention relates to a novel arrangement of machinery for breaking and cleaning flax, hemp, and other like fibre-yielding plants. It is also capable of being beneficially applied to the softening of fibres after they have undergone the scutching operation. The machine consists, mainly, of two pairs of gripping fluted rollers, which are operated in such a manner that the woody portion of the material under treatment is broken by a crushing action, and the broken fragments loosened from the fibres by a rubbing action of the flutes alternately in opposite directions. *Patent completed.*

2729. J. B. Palser. *Improved apparatus for manufacturing paper pulp and recovering the alkali used in such manufacture.* Dated October 9, 1862.

The object of this invention is to reduce straw and other fibrous materials to pulp in an economical and expeditious manner. The process may be simply described as the subjecting of straw and other fibrous materials to the action of an alkaline solution in rotating boilers under a pressure of from 110 lb. to 130 lb. to the inch, or thereabouts. The invention cannot be described without reference to the drawings. *Patent completed.*

2730. G. Simons. *Improvements in the manufacture of plates, rods, axles, tyres, and other articles that are required to be partly of iron and partly of steel.* Dated October 9, 1862.

The object sought to be accomplished by this invention is the manufacture of steel and iron united intimately to each other; but this, from the nature of these metals, is impossible when one of them is welded to the other. The inventor states that he has attained this object by the application of the principle of partial cementation. By conducting the cementing process in the manner described in the specification of this invention, plates and bars, both round and square, and other articles, may have one or more or all of their faces, or a part or the whole of their circumference, steeled, the other faces or the interior of the articles not having been at all subject to the carbonizing action. *Patent abandoned.*

2731. L. Hosch. *An improvement in the mode of constructing travelling trunks and portmanteaus.* Dated October 10, 1862.

In carrying out this invention, the inventor takes two thin sheets of suitable wood and glues them together, applying a sheet of canvas or other suitable materials between them, taking care to cross the grain of such wood, and this forms the cases of the shapes required. *Patent abandoned.*

2732. W. and S. Scholefield. *Improvements in apparatus for cutting button holes and other similar purposes.* Dated October 10, 1862.

In carrying out this invention, the inventors make an apparatus working on a pivot the same as the ordinary scissors or shears, but instead of the two blades cutting by the edges coming in contact, they fix a knife at the extreme point of the upper part of the cutters, making the said knife any suitable length, with a small tube at one end of it for the purpose of cutting or rounding the hole at the front end to receive the shank of the button. The said knife is secured to the upper part of the apparatus by set screws, whereby the inventors are enabled to adjust or regulate it as required when it becomes worn, or to take it out for the purpose of sharpening. At the end of the bottom part of the cutters they make a slot and fix a guide to work in it, which is adjusted to the length required by means of a graduated scale on the said guide, and when set to the proper length is secured by a screw, so that all the holes will be cut of the same length. And in addition to the guide they place or fix another guide or gauge with a stop or projection to regulate the distance required from the edge of the material to be cut. *Patent abandoned.*

2733. E. R. Green and J. Cockcroft. *An improved amalgamation of materials forming a substance suitable for printers' blankets, conductors used in paper making, packings for joints, and similar purposes.* Dated October 10, 1862.

In carrying out this invention, the patentees combine two or more lengths of paper, together with a solution of india rubber, or its substitutes, by spreading it between them and pressing them together. Or they put a texile fabric, such as linen, cotton, or woollen, between folds of paper; or they put a texile fabric, such as linen, cotton, or woollen, on the outside, with paper underneath, always making the different folds adhere with a solution of india rubber, or its substitutes, as above. In selecting the "surface" of the article to be used for printers' blankets, it must be adapted to the peculiar colours used by the printer, as some colours are strongly acid, some alkaline, others neutral. For the webs used by paper makers they prefer to use folds of woollen paper, with a textile fabric at the back. For washers for packing for steam joints, they join any suitable number of any of the above materials together, and submit them to pressure and heat or other drying process. *Patent completed.*

2734. G. Baguley and H. Greener. *An improved construction of insulator for telegraph wires.* Dated October 10, 1862.

The object of this invention is to secure telegraph wires in position on or in their insulating supports without wire bindings or other attachments as commonly employed. This the inventors effect by forming the insulator with a longitudinal slot for receiving the telegraph wire, and they gain access to the slot for the insertion of the wire by making a zig-zag opening in the side thereof. By this arrangement the tendency of the wire (through the continued action of the wind upon it) to escape from its seat is completely checked. *Patent abandoned.*

2735. J. Lowe and J. Harris. *An improved construction of propeller.* Dated October 10, 1862.

The object of this invention is to economize the power applied to the driving of ships' propellers. This result the patentees obtain by so modifying the form of the blades of the class of propellers that are known as screw propellers, in contradistinction to paddle-wheel propellers, as to prevent the churning of the water near the centre of motion, and at the same time to effect a reduction of the slip of the propeller, and of the vibration of the propeller shaft. In carrying out this invention, they use two, three, or more radial blades, and these blades they shape so that when viewed edgewise or endwise, instead of forming portions of the thread of a screw, they will present a curved line curling in opposite directions from the centre to the edges of the blade. *Patent completed.*

2736. H. A. Marinoni. *Improvements in apparatus for fixing type in the chases.* Dated October 10, 1862.

This invention consists in the arrangement and application of wedge or inclined pieces or quoins having rack teeth, forming thereon and fitting into a pinion or cylinder having indents to receive the teech of the rack. This wedge with rack teethis placed and abuts against the foot and sidestick or furniture and type, and the patentee disposes the cylinder between such rack, wedge, or quoin and the chase. The pinion cylinder has small inclined flanges embracing the chase to keep it in place, as also the quoin; a square hole is made in the centre of the pinion cylinder for the insertion of the key whereby to turn it. The pinion cylinder is also furnished with bearing surfaces, which bear and roll on the plain surfaces of the chase and on the quoin. By turning this cylinder it is propelled and rolls on the quoin and rubs along the chase by reason of the grip of the pinion on the rack teeth of the quoin, and in passing from the thin towards the thick part of the quoin, wedge, or inclined piece with a gradually increasing pressure locks and fixes the furniture and type firmly in place in the chase. *Patent completed.*

2737. W. C. Edge. *Improvements in velocipedes.* Dated October 10, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2738. D. S. Sutherland. *Improvements in constructing beams, girders, bridges, and viaducts.* Dated October 10, 1862.

The object of this invention is the construction of a beam, girder, bridge, or viaduct that shall be self-contained, while retaining the distinctive features of a suspension bridge, that is to say, the power exerted by means of the anchorage or otherwise in the maintenance of a suspension bridge is applied and diverted by the patentee in another form and direction, viz., within the structure itself. He effects this by means of a combination of compression or straining beams, and of suspension bars or tension rods. *Patent completed.*

2739. W. Weallens. *Improvements in surface condensers for marine and other engines.* Dated October 10, 1862.

This invention consists—1, in screwing one or both ends of the condenser tubes externally or internally, so as to admit of a screwed nut or cylinder of brass or other material to be screwed on or into one or both ends of such tubes, india rubber or other elastic material embracing the tube ends being introduced between the tube plate and the said nut, a recess being made in the tube plate to receive the same. The object of the second part of the invention is to effect the most advantageous distribution of water through the various tubes of surface condensers. The cold water chamber, into which the water is forced before going through the condensing tubes, is divided into two or more parts by division plates arranged at right angles, or nearly so, to the condensing tubes. These plates can be adjusted so as to increase or diminish the volume of water at any part of the condenser by means of screw levers or other mechanical appliances from the outside of the said cold water chamber where the condenser is in operation. *Patent abandoned.*

2740. T. Anderson. *Improvements in the construction of ships or vessels.* Dated October 10, 1862.

Under one arrangement, as adopted for a passenger ship or for carrying freight, the improved vessel consists of two hulls arranged parallel, the inner face of each hull forming a vertical line, in the same manner as if an ordinary hull was cut asunder longitudinally, and the open part of each half was shut in by a level facing of timber. These hulls are arranged at some distance asunder, and are connected together by a deck above, on which is built another, and the sides are enclosed in the usual way; the area thus obtained is of great extent, and may be fitted up with cabins, or set apart for cargo. The lower part of each hull may also be usefully employed for the stowage of freight, stores, or other similar purpose. In the broad longitudinal channel formed between the two hulls is fitted a central paddle wheel, and outside the hulls are fitted two other paddle wheels in the ordinary position. These propellers may be used either conjointly or otherwise, according to the speed at which the vessel is required to be driven. At the fore part of the vessel is built a cutwater, which is pendent from the underside of the lower deck. In passengers vessels the central part of the upper deck is occupied by a saloon, the elevated position of which affords every facility for admitting abundance of light, and obtaining complete ventilation, whilst the space outside forms an excellent promenade owing to the great width of the deck. *Patent abandoned.*

2741. J. J. Shedlock. *Improvements in gas meters.* Dated October 11, 1862.

In order that a wet gas meter may be rendered the more sure and perfect in its registration, the patentee surrounds the drum or measuring wheel with an annular float or air-tight vessel of sufficient capacity to displace a volume of water equal in weight to the drum, so that by possessing a buoyancy it can rise as the water rises, or fall as the water decreases in the case; or, more properly speaking, that the water always maintains the same level in the drum or measuring wheel. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated Dec. 22, 1862.

3414. A. S. Stocker, Wolverhampton, manufacturer. Improvements in rolling iron for the manufacture of tips and other articles.

Dated Jan. 15, 1862.

127. H. Turner, Leeds, leather strap manufacturer. Improvements in apparatus for preventing and curing blight, decay, disease, and rot in potatoes.

Dated Feb. 18, 1862.

450. J. Gray and J. Hudson, Botolph-lane. Improvements in the treatment of steatite, and in its application to certain purposes.

Dated Feb. 24, 1863.

496. H. Masters, Bristol, architect and civil engineer. Improvements in spools, bobbins, rollers, and similar articles.

Dated March 3, 1863.

601. J. Pollard, Leeds, commission agent. Improvements in warp dressing, and in apparatus connected therewith. (A communication.)

Dated Nov. 5, 1862.

622. W. J. and R. Watkins, Canal Iron Works, Millwall, engineers. Improvements in steam engines.

Dated March 6, 1863.

637. W. E. Gedge, 11, Wellington-street, Strand. Improvements in steam engines. (A communication.)

Dated March 11, 1863.

667. W. Wood, Monkhill, near Pontefract, York. Improvements in the manufacture and ornamentation of pomfret or liquorice cakes, rolls, sticks, and pipes, and other similar articles of confectionery.

Dated March 21, 1863.

753. I. M. Evans, Cefn Mawr, and W. T. Griffiths, Merthyr Tydvil. Improved means for ventilating mines.

Dated April 7, 1863.

872. J. Swinburne, Alfred Town, Ashford, Kent, and J. Stanley, Whitechapel-road. Improvements in steam engines and generators.

876. J. H. Johnson, 47, Lincoln's-inn-fields. Improvements in machinery or apparatus for drying grain, applicable also to the manufacture of malt. (A communication.)

880. J. Howard, E. T. Bousfield, and J. Pinney, engineers, Bedford. Improvements in steam engines, and in the means of applying the same to the tilling of land, also in apparatus to be used with such engines in the tilling of land.

Dated April 9, 1863.

896. G. Spencer, 2, Lousanne-villas, Queen's-road, Peckham, civil engineer. Improvements in preventing incrustation in steam-engine boilers.

900. J. R. Burton, K.H.A., Vice Admiral in Her Majesty's Navy, 15, Park-square, Regent's-park. A new method of, and apparatus for, cleansing ships' bottoms.

Dated April 10, 1863.

908. S. Shelmerdine, Stockport, and J. Dransfield, Oldham, hat manufacturers. Improvements in the ornamentation by printing of felt hats.

912. J. Gimson, Leicester, engineer. Improvements in screw-cutting lathes.

914. H. Caudwell, Oatlands House, Shillingford, gentleman. Improvements in the construction of vessels of war, part of which improvements is applicable to fortifications.

Dated April 11, 1863.

916. J. Lockwood, Batley, rag merchant. Improvements in steam boiler and other furnaces.

918. W. Samuel, Liverpool, watch manufacturer. Improvements in, or applicable to, railway carriages to mitigate or lessen the effects of collision to passengers.

920. W. Clark, 53, Chancery-lane, engineer. Improvements in separating ores from their gangues, and in apparatus for the same. (A communication.)

922. A. F. Maclure, Glasgow, machinist. Improvements in looms for weaving figured fabrics.

Dated April 13, 1863.

924. J. Ramsbottom, Crewe, engineer. Improvements in machinery for hammering, rolling, and shaping metals.

926. A. Rolfe, Amwell-street, Pentonville, merchant. Improvements in means or apparatus for propelling carriages on railways, tramways, or on common roads..

932. T. Mallinson, Globe Works, Manchester, machine maker, and P. Williams, machinist. Improvements in machinery for opening, cleaning, carding, and grinding or sharpening cards used in preparing cotton and other fibrous materials.

Dated April 14, 1863.

934. G. Berry, 19, Buttesland-street, Hoxton, gentleman. Improvements in locks.

936. W. and J. Keats, Street, Somerset. Improvements in the manufacture of boots, shoes, or other coverings for the feet.

938. J. Keats and W. S. Clark, Street, Somerset. Improvements in sewing machines.

942. J. Smith, Edward-street, Wentworth-road, Bow-road East, engineer. Improvements in furnaces and boilers for the generation of steam, partly applicable also for other purposes.

Dated April 15, 1863.

944. E. P. Colquhoun and J. P. Ferris, 1, Lawrence Pountney-hill. Improvements in fire bars for the purposes of steam boilers and fire grates.

946. W. Clark, 53, Chancery-lane, engineer. Improvements in apparatus for the transport of goods. (A communication.)

948. A. Marriott, High-street, Higham Ferrers, Northampton, engineer. Improvements in boilers for heating buildings, and in regulators for the same.

950. H. Heaton, Manchester, smith and wheelwright. Improvements appicable to presses for baling purposes.

Dated April 16, 1863.

954. J. B. Watts, Birmingham, sword cutler. An improvement in steel sword hilts.

956. I. Baggs, Cambridge-terrace, practical chemist, and W. Simpson, Tovill Upper Mills, manufacturer. Improvements in purifying and treating coal gas, sulphuretted hydrogen, and other gases containing sulphuretted hydrogen, and in obtaining sulphur, sulphuric and other acids in such treatment.

958. S. Moulton, Bradford, India-rubber manufacturer. Improvements in apparatus or means for lessening the recoil of cannon.

962. F. A. E. G. de Massas, Hoxton, civil engineer. Improvements in smut machines, and in machines for cleansing and peeling grain and seeds.

Dated April 17, 1863.

968. R. H. Lawson, Victoria-terrace, Victoria Docks, and W. Darlow, Victoria-place, North Woolwich-road. Improvements in apparatus or means for obtaining motive power.

970. C. Turner, Airedale Felt Mills, Hunslet. Improvements in the manufacture of felted fabrics.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, April 28, 1863.

209. C. Stopford. Hats and other coverings for the head.

261. B. J'A. Bromwich. Motive power.

272. A. Pritchard. Preserving the contents of packages from air, water, or damp.

288. F. Tolhausen. Apparatus for cleaning the beams of mules and spinning frames, collecting the dust and waste thereof, and also for cleaning the flooring underneath the mule carriages. (A communication.)

382. W. Clark. Bearing surfaces of shafts and other axles. (A communication.)

500. J. Hawthorn. Handles for doors, drawers, and other means of enclosure.

667. W. Wood. Manufacture and ornamentation of pomfret or liquorice cakes, and other similar articles of confectionery.

725. W. E. Taylor. Machinery for reeling, winding, warping, and beaming yarn.

865. T. Burrow. Machinery for combing or dressing silk, flax, wool, hemp, China grass, and other fibrous materials.

880. J. Howard, E. T. Bousfield, and J. Pinney. Tilling of land.

900. J. R. Burton, K.H. Cleansing ships' bottoms.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed April 24, 1863.

2865. L. Groux.
2889. T. Pilgrim.
2801. J. J. Ridge.
2892. P. E. Placet.
2893. G. Lindemann.
2898. E. Hooper.
2900. E. and A. Tatham.
2903. E. S. Tudor.
2906. T. Sutton.
2907. A. Ripley.
2908. A. Shanks and F. Kohn.
2918. W. E. Gedge.
2922. F. L. Stott.
2926. H. Eastwood.
2927. F. Gregory.
2931. P. Giffard.
2940. D. Spink.
2955. J. W. Taylor.
2962. F. Tussaud.
2966. F. Trachsel and T. Clayton.
2970. T. O. Clark.
2985. J. Shirt and C. Briggs.
3001. J. J. Laveissière.
3010. C. O. Heyl.
3021. E. Sonstadt.
3029. R. R. Holmes.
3049. J. Faulding.
3055. G. W. Rendel.
3065. C. G. Kopisch.
3075. E. Kirby.
267. J. Pouncy.
395. J. A. Schlumberger.
516. H. Wilde.

Sealed April 28, 1863.

2942. C. Gubbins.
2969. W. Clark.

The *Times*, May 7th, speaking of Benson's Watches in the Exhibition, says :—"Undoubtedly, however, the finest show in this respect is made by Benson, who offered prizes for designs for watch-cases at the South Kensington Museum, and who by this means has secured some of the most exquisite ornamental details for watch-cases that are shown in the building." Chronometer, duplex, lever, horizontal, repeaters, centre seconds, keyless, split seconds, and every description of watch, from the plainest to the highest quality of which the art is at present capable, and adapted to all climates. Benson's Illustrated Pamphlet on Watches (free by post for two stamps) contains a short history of watchmaking, with descriptions and prices. It acts as a guide in the purchase of a watch, and enables those who live in Scotland, Ireland, Wales, the Colonies, India, or any part of the world, to select a watch, and have it sent free and safe by post. J. W. Benson, Prize Medallist, 33 and 34, Ludgate-hill, London.—Established 1749.—[Advt.]

MECHANICS' MAGAZINE.

LONDON, FRIDAY, MAY 8, 1863.

ANALYSIS OF CAST IRON.

Few subjects present features of greater importance than the best means of obtaining accurate information regarding the constituents of any sample of cast iron. From the ironmaster, who from the crude pig manufactures sheets, rails, bars, the panoply of an armour-plated frigate perhaps, to the civil engineer, the success of whose works may depend on the ultimate strength of columns and girders of cast iron—all are concerned; by all any further progress in the means of obtaining an accurate analysis of a material so largely used, must be hailed as a welcome aid to their labours. Hence, if we regard the subject in this point of view, everything, no matter how apparently trivial it may seem, which tends to throw light on an admittedly difficult subject, must be regarded as of more or less importance. We would call the attention of our readers to a phenomenon which we have found sufficiently obvious, yet has not yet, we believe, received any share of attention from those who might possibly draw valuable deductions from it.

When melted pig iron is tapped into a ladle in moderate quantities, so that excessive heat may not prevent pretty close observation, it will sometimes be found to boil violently, sometimes its surface is calm from the first. Now, if this molten iron is allowed to stand a few minutes until it becomes perfectly quiet, and is then carefully skimmed clean, we shall find that a beautiful irridescence covers its entire surface, due to the constant breaking up of the extremely thin film of oxide formed on the iron. This irridescence, frequently called by moulders the "pattern of the iron," may, on close inspection, be found to consist of a multitude of many sided or rayed stars, in constant motion; breaking up and vanishing, and forming anew with the velocity of thought, and almost eluding the eye. It is a matter of extreme difficulty to determine the number of rays in each figure; we believe we are correct in saying five; one thing is certain that their shape and character, is invariable with every species of iron with which we are acquainted.

This much premised, we would call attention to what we are inclined to consider as a proved fact—namely, that the *size* of the different figures which make up the "pattern," in all cases, depends on the size of grain of the iron when in the pig. Thus, hematite, which is a large-grained iron, will, when melted, present a large pattern. Fine-grained irons, such as the grey forge pig of some of the Staffordshire works, give an extremely small pattern. This distinction is, we understand, so well marked, that in some cases a glance at the melted iron will enable an accurate opinion to be formed as to the size of grain in the pig.

We have already said that it is almost impossible to determine exactly the form of the figures presented by the irridescence. Might not instantaneous photographs be taken, which would give us all the information we require on the subject? We throw out the hint to those skilled in that department of science. We believe it might be possible to obtain photographs from the surface of vessels containing different samples of melted iron, whose comparison might lead to valuable results. As it is, it seems clear that the character of the figures bears some relation, more or less fixed and determinate, to the laws regulating the crystallization of the iron on cooling; and in this belief, without wishing to be understood as making any positive assertion on the subject, we would suggest it to those occupied in scientific research, as one which while certainly not devoid of interest, may in able hands lead to useful practical results.

PAYMENTS FOR THE PROTECTION OF INVENTIONS.

In response to the ill-judged attacks lately directed against patent rights, the question as to the existence or abolition of these laws has been completely brought before the public. The matter appears to us to have been discussed almost *ad nauseam*, as the majority of men of sense have long since made up their minds on the question. In any case, the Legislature would look twice before it abolished a system that has existed for nearly three centuries in our own country, and has been imported into every civilized part of the world.

At the same time, the practical questions touching upon patent right have so many and such varied bearings, that it is important for the interests of inventors that these inquiries should be well ventilated before any alteration is made in the existing law. As is generally known, a Government Commission of eleven gentlemen has been formed to ascertain the best means to remedy existing abuses. Seven out of the eleven persons composing this Commission are lawyers; and when it is remembered that nearly £10,000 are annually drawn by the Crown lawyers from the Patent Fund; and if we bear in memory the enormous incomes derived by the legal profession from disputed patent cases (many patent suits have cost £20,000), it will be seen how important it is for the public interested in patent property to think and act for itself in this matter. Mr. Thomas Webster, the well known patent barrister, has already set patentees a good example. This gentleman lately read a Paper before the Inventors' Institute, "On the Effect of the Periodical Payment, at the end of the Third and Seventh Years respectively, on the Patent System, and Interests of Inventors." The questions touched upon in the Paper were then discussed, in an interesting but somewhat desultory manner, by the members of the Institute. We have not space to treat fully on these inquiries, but it may be interesting to briefly allude to the various plans of payments for patented inventions that have been proposed and carried out in different countries.

These various systems may be divided into three several heads:—1. Gratuitous, or, at least, very cheap patents. 2. One payment for the whole duration of the patent. 3. Periodical and increasing payments; or annuities, either constant, or progressively increasing. Most of the above-enumerated systems are represented in the different countries where invention is regulated by a patent law.

1. In Prussia, in some of the German States (*e.g.*, Hanover), and in Denmark, patents are granted almost gratuitously.

2. In Russia, Spain, Portugal, Sweden, Holland, Bavaria, and in the United States, a single payment is at once required, covering the whole duration of the patent. In no case, however, do these payments at all approach in amount the sums demanded in our own country.

3. In England, in Saxony, and in the Papal States, there are two or three progressive payments spread over the total duration of the patent. The payments in France and in Wurtemberg are made in the form of annuities; in the first country of 100f. per annum. In Belgium there are increasing annuities. In that kingdom 10f. are paid the first year, 20f. the second year, 30f. the third year, and so on till the *twentieth* year, by which time the payment of course amounts to 200f. It would, no doubt, be valuable to our Patent Commissioners to obtain full evidence from foreign countries as to the working of their patent laws. The question, whether an invention should obtain a gratuitous or, at least, a very cheap patent, is one fraught with great difficulties in its solution. It forms a great question by itself, and we have not space to fully discuss it here. Patents have to pass a very severe and stringent examination in countries where this system exists. This examination is so severe in Prussia that its stringency amounts to a positive grievance. With respect to gratuitous patents, we must remember that all property in civilized society is subject to taxation, and there is no reason why patent property should be exceptionally exempted. If the price of patents be much lowered, a Patent Examining Commission would have to be formed to stem the tide of the innumerable resulting applications for patents, and there are many practical difficulties in the formation of a Board of Examiners.

With regard to the second system, that of a single payment, once and for all, it is, perhaps, objectionable, both for the patentee and the public. The patentee has to pay a lump sum, often very heavy in amount, before he has the least protection in his undertaking. If the patentee be unable to carry out his invention; and there is a very great distance, and a long and difficult journey, between an idea and its practical realization; the patent still exists as a stumbling-block to the progress of others. Very few would be found willing to undertake the pecuniary risk and difficulty of experiments if all the honour and much of the profit were to go into the hands of other people.

The progressive system of payments seems evidently to be the most just and rational. When examined before the Patent Committee in the House of Lords of 1851, Messrs. Rendel, Fairbairn, Prosser, May, Westhead, Mercer, Cole, Hodge, Spence, Fothergill, and Fairrie were all in favour of progressive payments. The only objection appears to have been brought by one gentleman, who, in answer to the question as to whether any injurious effect was produced by periodical payments upon inventions, stated that, "Many inventions, though they have not been at all successful up to the third year, are still very ingenious and very good inventions, and consequently the payment might come upon the inventor, and very likely would, at the time when he had been expending money without reaping any profit; and the capitalists and others engaged in the concern would be very likely to throw the matter over altogether rather than pay the tax." It appears to us that the strength of this objection would vary with the amount of the banker's account of the "capitalist;" and it is thus a case coming under the head of the great question of cheap or dear patents.

There cannot be a doubt as to the value of the progressive system. An invention, while young, and the inventor while yet poor, ought both to be tenderly treated. At the same time, it is in the interest of the inventor himself that we would not advocate greatly cheapened patent protection. We would prefer that the money should be spent upon the making of complete models of mechanical inventions; of careful samples of chemical discoveries, &c. The outlay should also be returned to the country in the shape of a cheap and easily accessible publication of previous inventions.

As the country is so much benefited by the patent system, a system which, by supporting manufacturing industry, directly increases the wealth of individuals, and indirectly the wealth of the State, it seems utter folly to require a heavy sum from an inventor just entering upon a fresh and difficult enterprise. On the other hand, the public must be protected from "fishing" and obstructive patents. It has been proposed to levy an income tax on the profits of inventions. The difficulties in raising such a tax will be at once apparent. It appears to us that the Belgian system of progressive annual annuities is the most equitable to all the parties concerned—patentees, the public, and the State. A fine should be levied for unpunctuality in the payments; it is iniquitous to confiscate a patent on account of a short delay in a payment. If all kinds of property were thus liable to confiscation, estates would change hands rather oftener than at present. An annual progressive increase completely takes into account the success or non-success of the patent; and an invention, while in the bud and undeveloped, would receive more tender handling than under the present system, by which an inventor often has, on an average, to pay £100 by the time his patent has lasted only three years. While advocating the general principle of progressive payments, we would suggest with regard to the present fees in England, the abolition of the Government stamp duty of £50 at the end of the three years; and the conversion of the £100 stamp into one of £80, at the expiration of the seven years.

THE SPITHEAD FORTS.

THE Spithead forts, which we did our best to oppose last session, and with some success, are again proposed to be erected. The repulse of the Federal iron-clads by the Charleston batteries has revived this question, and aroused in the Government officials the hope of carrying out the great Portsmouth contract job, involving an expenditure of more than a million, which for a time eluded their grasp. The usual machinery to play on the public mind, is set to work; and we are assured, as if it were a gratifying announcement, that estimates for resuming the construction of those useless harbour defences will shortly be laid before Parliament.

Last year we succeeded in showing the doubtful utility of these works. We hope to be again equally successful. Since then the circumstances affecting the case have undergone no change. The destruction of one badly constructed and inefficiently armour-plated gunboat, and the disabling of two little "Monitors" carrying two guns each, are events which, properly considered, have not the slightest bearing on the question. The disastrous result of the Federal attack on the Charleston forts only proves the miserable inefficiency of the iron-clads with which the attempt was made.

The real point for consideration is, which is the best kind of defence for a broad sea channel leading into a harbour, fixed or floating batteries? Here is a million of money or more to be spent for the protection of an important arsenal. Shall we cast it into the sea to build forts on sandbanks, where they must remain immoveable, or shall we employ the same sum to build five or six floating batteries of transcendent power? No doubt exists that our naval engineers can produce moveable fortresses calculated to resist and carry the heaviest ordnance that can be constructed.

There is evidently a design to take Parliament by surprise, and carry a resolution for the construction of the Spithead forts by raising false issues. The members who understand the question and influence the House, can only save the country from a useless expenditure by constant vigilance, and especially by laying the facts plainly before the country.

In referring to moveable defences, we do not mean line-of-battle ships, frigates, or sea-going cruizers of any class. We mean literally floating fortresses. Of this class of structure, which is of more importance for the protection of our shores than the whole of our existing fleet, not one yet exists. To this grave fact we draw public attention. If we are to spend another million or two for harbour defences, let it be applied in the most efficient way.

The guns of a fort, at the entrance of a channel a mile wide, can only reach invading ships at long range, which immensely diminishes the efficacy of their fire. The number of shots from the Confederate forts which struck the Federal iron-clads was 50 to 60 on each vessel, and yet they did comparatively little damage. If floating batteries carrying 300-pounders, such as smashed through-and-through the Chalmers' target the other day, had defended Charleston harbour, there is little doubt every one of the "Monitors" and the "Ironsides" frigate, with their weak system of armour, would have been sunk. Or if the Federal squadron had been composed of a more efficient class of iron-clads, they would have run the gauntlet, passed by Forts Sumter and Moultrie, and laid Charleston in ashes.

Much stress is laid on the obstructions placed in the channel to stop the enemy's vessels. But the use of floating instead of fixed batteries does not prevent similar obstructions being laid down. On the contrary, it would render the value of such obstructions much greater. Imagine the Federal ships brought up in the channel by rows of stakes, chains, and booms, with a fleet of Confederate floating batteries inside, pouring in broadsides of 300-pounder steel shot at 200 or 300 yards, would not the chances be infinitely greater against the attacking force, than under any fire at 1,200 yards? This is the true way of looking at the question of the Spithead forts. It was shown, during the last discussions, that the range of any effective fire from them could never be less than 1,000 yards, as the enemy would keep in mid-channel, which exceeds that distance from the proposed site of the forts.

Lord Hardwick went out of his way to cite instances of the failure of fleets in attacking land batteries; but these are accounts of the defunct school of naval warfare, when wooden vessels knocked their heads against stone walls. *Nous avons changé tout ca.* Iron walls afloat would go alongside any of the fortifications the noble earl alluded to, knock in the embrasures, and drive the artillerymen from the guns, as the "Merrimac," with only four guns, did in Hampton Roads. It is really idle to bring up old world stories about wooden ships in this iron age. It would be just as reasonable to refer to the battles of Actium or Lepanto as events for estimating the offensive power of iron-clads.

We cannot dismiss this subject without reverting to the five new iron-clads for which a million and a half was voted. The question arose whether they were to be built of iron or wood. There was a unanimous feeling in the House that they ought to be iron ships, and a determination not to allow any more iron-clads to be built of wood was plainly evinced. To conjure the rising storm, the Premier gave a pledge that if the point were left to the discretion of the Admiralty, the money would be employed in the way most beneficial to the country. He, moreover, stated that before any part of it was expended, experiments would be made with the "Valiant" and "Royal Oak"—the former an iron, the latter a wooden armour-plated ship—in order to determine which class of men-of-war was most suitable to the service. It was understood that these experiments should extend, not only to the sea-going properties of the new vessels by testing them on a cruise in search of gales, but to the trial of a wooden ship target at Shoeburyness. Neither of these promises has been fulfilled. One is already broken; for a few days ago it was announced that the "Belvidera," a wooden ship, was laid down to be converted as one of the five new iron-clads. This Palmerstonian method of first evading a hostile vote and then deceiving the country, is deplorable. When will the House of Commons have the public spirit to put an end to it?

The experiments on targets with explosive shells render the "iron *versus* wood" question one of vital importance. The results proved that Whitworth and Armstrong shells will penetrate the "Warrior" class of armour, and with their incendiary charge will set a wooden ship in flames. Is Government to be allowed to spend more money on vessels costing a quarter of a million each, which cannot fail to be destroyed the first time they go into action?

If the country is satisfied that Portsmouth Arsenal ought to be protected against the possible attack of a fleet of iron-clads, it will be ready to grant the sum required for that purpose. Parliament will raise no difficulty. The Government proposition, which probably will be a loan on terminable annuities, will be readily acceded to. But it will be the business of the members, who understand the question, to demand that the money be applied to the right class of defences, and to the construction of those works which are the most useful and urgent. The reasons we have stated leave no doubt that floating batteries are far more useful and urgent than fixed forts on sandbanks. The Chancellor of the Exchequer will be disinclined to increase his Budget. There is little doubt the money intended to be asked for, will be, as we have suggested, in the form of a loan. No possible reason can be adduced why the sum required for the construction of floating batteries should not be raised in that way as well as for the construction of forts. Already we perceive an attempt is being made to impress the public with the idea, that a large sum having been spent on the Horse, Noman, and Surbridge marine forts, it would be deplorable that that outlay should be lost to the nation. Never was there a worse argument. The very reason which induced Parliament to suspend the works—viz., the conviction of their inutility—is the best reason for abandoning them altogether. We have a proverb which exactly applies to this case—"What is the use of throwing good money after bad?"

HIGH-SPEED STEAM ENGINES.

SMEATON, Morin, Poncelet, and many others have given us accurate rules for the construction and speeds of water-wheels; rules which must be observed, if we wish to obtain the highest practical results, the nearest approach to theoretical perfection. Such rules are invaluable, because the mechanical effect of water depends solely on gravity-pressure, which is the result of gravity, or on a combination of both; hence, a certain velocity, to a great degree fixed and determinate, will invariably give the best results with any particular description of water-wheel; for, it is sufficiently evident, that if its circumference travel at the same speed as that due theoretically to the water under the action of gravity, no useful effect can be developed; and, on the other hand, if the entire weight of the water be claimed, no motion, and, consequently again, no useful effect, can be realized. These laws are, or should be, so well understood, that we feel inclined to apologize for their introduction here; still an allusion to them may help to simplify matters further on.

Smeaton, however, and other writers on the same subject—knowing doubtless how difficult it is to make invariable laws, no matter how correct, suit varying circumstances—permits a certain degree of latitude in the observance of his rules, and, steering between what is theoretically right and practically wrong, tells us that the best speed for the periphery of a water-wheel lies between 6 ft. and 3 ft. per second—a difference considerable in amount, yet rendered necessary by the varying diameters of different wheels. The reasons for such rules are sufficiently evident; simple inspection enables us to appreciate them.

But when we come to treat of steam—a subtle fluid, acting wholly by pressure, and flowing through passages, and from vessel to vessel, with a speed which is practically instantaneous—the question whether fixed constructive rules are valuable, or even necessary, when applied to machines for which it furnishes the motive power, assumes a widely different aspect; and we do not hesitate to assert that a blind adherence to such necessarily empirical formulæ is not only a bar to progress, but simply absurd on the part of the constructive engineer. It rather causes him to gaze at his subject from only one point of view, and adopt but one mode of construction for all sorts of circumstances; hence, many engineers look on high piston speed as a heresy, because it is opposed to the rules laid down by Watt and others when steam was yet in its infancy; they thus continue to apply rules written long ago to engines of a construction never contemplated by their framers—rules, the reasons for which indeed are sufficiently doubtful, even when applied to the cases contemplated, but when adopted in all their integrity, amidst the exigency of modern practice, are productive of the most injurious results. Smeaton's rules differ in resting on a good foundation, and being applicable to every description of water-wheel; we cannot say as much for Watts'—applied to the steam-engine. One of them—that regulating the speed of pistons in condensing engines, and applied in all its force to non-condensing engines by others—we regard as especially unsuited to modern practice.

This rule fixes the speed of pistons at 240 ft. per minute as that theoretically best for all engines of the larger class. Most works on the steam-engine, too, contain rules given with the most painful minuteness for ascertaining the correct speed for a certain length of stroke; in most if not all cases, such rules, if not founded on error, can at least be departed from to almost any extent with the best results; modern experience daily proves the correctness of our assertion.

Granted that we have steam enough and pressure enough in our boiler, we can have but two circumstances to dictate the speed at which any engine can be driven—the resistance produced by momentum in the reciprocating parts, which may be so excessive as to knock the engine to pieces; or the size of the pipes, ports, or passage, through which the steam is led to or from the cylinder. We have seen that any increase in the speed of a water-wheel above a certain point must result in loss of useful effect, because, so to speak, the water cannot follow fast enough; but nothing of this kind can occur with steam until the speed becomes so excessive as to be immeasurably beyond all practical requirements. No one will be rash enough to assert that the pressure on the piston can be less than that on the lid of a cylinder, until a speed almost infinite is attained.

We have no evidence to show that any other considerations than those due to the best theoretical speed for the pumps, and a due allowance of time for condensation, ever influenced Watt in drawing up rules which have met with a world-wide acceptation. 120 ft. per minute is a high speed for large pumps; in fact, just about the highest at which they will be found to work quietly and satisfactorily without a resort to extraordinary expedients, such as permitting a pause at the end of the stroke, as in deep mine pumps, quite inapplicable of course to rotary engines of which we are speaking; and as Watt's air-pumps generally worked at "half-beam," this is just the speed of their pistons. But it is quite evident that many plans might be, and indeed are daily, resorted to, by which the speed of the steam piston is rendered quite independent of that of the pumps; nevertheless, any departure from the old established speeds is strongly condemned by a numerous class of engineers.

Now we do not for a moment mean to assert that, *cœteris paribus*, 240 ft. per minute is not just as good a speed as any other, faster or slower, which we may choose to adopt. We do not believe that there is any fixed rule for piston speed; but we do believe that a blind adherence to a low speed of piston, causes the general adoption of cumbrous, heavy machinery, weighing and costing much more than it ought, and in many instances inducing an extra expense in the necessity for machinery, otherwise needless, to get up the speed of the mill or other works driven by the engine, and in addition rendering it necessary to employ a piston, whose size, in order to obtain power enough, is an effectual bar to any extended use of expansion, owing to the shock of high steam on such a large surface.

Most writers on expansion mention different expedients to overcome the varying speed of the engines; strange, that, almost without exception, they totally disregard in all their calculations the question of piston speed or the number of strokes per minute. Now, machinery running at a high speed cannot have its velocity changed instantaneously. A certain amount of time is necessary to produce retardation or acceleration in any appreciable degree; the same is true even of a heavy fly-wheel. It is quite possible to drive a piston at such a speed with a short stroke, that, though expanding its steam ten or twelve times, the engine will make its strokes so quickly that the momentary variation in force through different parts of the stroke will not have time to influence the machinery driven, to any appreciable extent; the speed once attained, will be equable; and at the same time, the size of the piston will be so much reduced, that no injurious effect can be possibly produced by the effect of high pressure steam on its surface. Indeed, no means of overcoming this evil of the first shock of the steam presents itself in as favourable a light as the use of a very small piston travelling at a high speed.

All parties admit that by a multiplication of cylinders we may attain any desirable amount of regularity of speed, no matter what the expansion, simply because the whole amount of irregularity or variation of force is shut up and divided amongst a number of strokes, instead of being all concentrated, so to speak, in one or two. But this subdivision can just as well be obtained by driving a single piston at such a speed, that the number of strokes performed by it in a minute may equal the aggregate number of strokes performed by a number of pistons giving out the same horse-power. Thus, if we suppose an engine working at twenty revolutions per minute, and say, for the sake of simplicity, that the speed shall vary twice in each half-revolution, it is evident that there will be eighty variations in force per minute, and each variation, occupying something like three-quarters of a second, may very easily overcome the inertia of the machinery driven, and consequently cause a considerable variation in speed. If now we drive the engine at one hundred revolutions per minute, the changes in force will be, to all intents and purposes, instantaneous, and cannot possibly produce any material effect, except on very light machinery, when the introduction of a second cylinder will at once give us all we can desire.

But, further, it must be remembered that the pressure on a crank pin of a high-speeded engine is never identical with that on the piston—indeed, with a heavy connecting rod and piston, the strain on the crank pin frequently exceeds, at the latter end of the stroke, that due to the initial pressure of the steam at the commencement; thus, another element is introduced, so important that it is quite possible to construct an engine which could not give a perfectly equal speed without expanding very considerably. In fact, we have a practical proof that such is the case, in a pumping engine, the speed of whose piston is tolerably uniform throughout its stroke, although the steam is expanded six or eight times; we have seen a locomotive jacked up, working at about 120 revolutions per minute, and expanding its steam six times, when driving all the machinery of a repairing shop with a regularity of speed which we have seldom seen equalled.

As to loss of power by condensation in the cylinder, everything is in favour of a high piston speed. A given weight of steam can only produce a certain amount of useful effect, whether we make it give out that effect in an hour or a minute. In a slow-speeded engine, the cylinder, instead of being kept at an equable temperature, has ample time to grow warm on the entrance of the steam, and cool while it does its work. The transitions in temperature, like the variations in force, are too short-lived, in an engine rising many strokes per minute, to permit any such result; in consequence, a very considerable gain in this respect has always been found to attend the use of a high speed. It is not so much loss of heat by radiation from the outside of the cylinder that is to be dreaded, as loss of heat by radiation into the condenser or atmosphere from the inside, which is also lowered in temperature by the expansion of the steam within. When meeting such difficulties, a quick reciprocation, a moderate amount of superheating, and a cylinder carefully clothed all over, ends as well as sides, will always secure the best results.

Modern practice seems to turn to the path we point out. In the locomotive we see an utter disregard for those rules, which we have stigmatized as defective, attended with the best results. There we see a pair of small cylinders giving as much useful effect as colossal machinery, while the consumption of fuel is reduced to some three or four pounds of coal per horse-power per hour. We believe that in the increase of piston speed, and in the multiplication of *uncombined* (in the McNaught sense of the term) cylinders, the real road to successful practice will be found; as by these means alone can we avail ourselves of all the benefits of expansion without extravagant first cost. No belief should obtain that a high-speeded engine is subject to an injuriously greater amount of wear and tear than one rising at slower speed; it is merely a question of workmanship and design, and our readers may rest assured that to modern English engineers this part of the question presents no difficulty.

THE QUANTITATIVE PROGRESS OF THE IRON MANUFACTURE.

From the year 1840 to 1860 the production of crude iron in England rose from 1,400,000 tons to 4,150,000 tons. It is not improbable that this amount will be increased in the course of the present year to five millions of tons. Nine years ago (in 1854) the quantity of crude iron produced in England was more than 3½ millions of tons. The quantity of malleable iron came up to nearly 2 millions of tons; at the current prices, this was worth 25 millions sterling; 242,000 steam-horses' power, and 238,000 operatives were employed in the manufacture. There is thus more crude iron manufactured in Great Britain than in all the rest of the world put together. France and the United States come next, as regards quantity of production; Prussia and Austria then follow. The times are thus greatly changed from those when, as Homer sang,

> A mass of iron, ...
> Rude from the furnace, and but shaped by fire,

light enough, in fact, to be carried away by one man, could be offered as a prize to the heroes competing at the funeral games of Patroclus.

Charcoal was, at one time, the only fuel thought capable of making good iron, but its scarcity and high price set a narrow limit to the quantity of iron that can be produced by the employment of this combustible. In those countries where wood is still plentiful, such as North America, Sweden, and Styria, &c., charcoal continues to be used, and the very best iron is the resulting produce. In England charcoal is only employed for converting malleable iron into plates and bars for tinning, and for a few other purposes for which the very best iron is required.

What may be called the first great epoch in the manufacture of iron dates from the application of a "flux," or of a substance that will fuse in combination with the earthy matter of the ironstone; the separation enabling the disengaged metal to flow freely from the furnace. Limestone is the flux that is almost universally used. The late Mr. Truran, in his work on the iron manufacture, states that chalk is made use of in some of the blast furnaces in the neighbourhood of Newcastle-upon-Tyne, but he believed that it is the only locality where chalk is so employed. As is generally known, the limestone is almost always found in close proximity to the iron ore and coal. In South Wales and Monmouthshire the limestone lies only a short depth below the seams of coal and iron stone. The quantity of pure lime contained in the stone determines its value as a flux. The chalk used as a flux in the Newcastle furnaces is stated to contain more than 50 per cent. of lime. The expense of this flux is, of course, greater than that of the limestone generally found below the coal and iron beds, as it has to be fetched at great distances from the iron-making districts. The limestone flux is generally at once charged into the furnace after the blocks have been somewhat broken up. In some iron works, however, the lime is utilized in a caustic state by previously being calcined in kilns similar to those used for the calcination of ores. It is doubtful whether the Romans used a flux in their iron-making. It is to be inferred from the quantity of iron found in the "cinder" of the still extant old Roman workings, that a flux was not used by the conquerors of the world. The name of the man who first used a flux is unknown. Like many other valuable inventions, its date is unrecorded.

It is noticeable that the first application in England of cast iron seems to have been to ordnance. This appears by a patent granted to Ralph Page and Peter Baude in the 35th year of the reign of Henry VIII (1543). The guns were cast at Backsteed, in Sussex. The Bessemer process for the manufacture of steel and iron also bids fair to form an epoch of itself. Like Ralph Page, Mr. Bessemer appears to have had mainly in view the production of a tough metal for long range ordnance. Significant but melancholy coincidence; illustrating most forcibly that intellectual and moral progress do not advance in parallel lines. Just as Ralph Page's charcoal pig-iron superseded the bronze cannon of Cressy, so will the Bessemer steel supersede all other materials for making cannon; and the progress of three centuries has thus resulted in giving man improved means for destroying his fellow-men.

The second great epoch in iron manufacture may be said to date from the year 1621, when Lord Edward Dudley obtained his patent for "the misterie and arte of melting iron ewre, and of making the same into cast workes or barrs with sea coles or pit coles in furnaces with bellowes." An account is given by Dud Dudley of his father's patent in the former's work entitled, "Metallum Martis."[*] There were two projectors previous to Lord Dudley, but he seems to have been the first successful patentee connected with the manufacture of iron. In the Act passed in 1628 against Monopolies (21 James I., chap. 3), Lord Dudley's patent, amongst others, is expressly excepted from being repealed by this Act against Monopolies. These exceptions form the foundation of patents for invention.

Dudley was persecuted on account of his discovery, and his works were destroyed by mobs. His process lay dormant a century after his death. The invention was perhaps premature, and at any rate it only came into use about the year 1740. The Governments of those days looked upon the iron manufacture as the natural enemy of the oak forests that formed the wooden walls of Old England. By the year 1740 the home manufacture had sunk to less than 18,000 tons per annum, under the united pressures of a diminishing supply of charcoal and of legislative discouragement, while the troubles of the preceding century had so checked industrial undertakings that the imports of iron did average more than from 30,000 to 36,000 tons in the year 1740. By means, however, of improved blowing apparatus, Lord Dudley's invention was about this time turned to full account. In the interval between 1740 and 1788 the produce of iron was raised to nearly 70,000 tons per annum, and the imports increased to upwards of 50,000 tons. At about this period also, the impress of Watt's magic hand began to make itself felt on the iron manufactures, and the completed steam-engine came to be applied to raising the coal, the ore, and the flux from the mine, to blowing the furnaces, and turning the rolls, &c. Thus the steam-engine, while it increased the demand for iron, at the same time facilitated its production in large quantities, until at last, as within late years, more iron is employed in the production of iron than could be furnished by the whole country in the beginning of the present century.

It is only within the last few years that raw or uncoked coal has been used for smelting iron. As is well known, the volatile gases are expelled from the coal by the process of coking, and the carbon alone remains. Mr. Truran states that when this process has been carelessly conducted he has seen from one-fourth to one-half of the carbon thrown away. The loss is but small when coking is properly conducted. Only few descriptions of coal are, at present, considered fit to be employed in iron smelting without being first coked. The bituminous and semi-anthracite coals are generally coked before being charged into the furnace. The semi-bituminous and pure anthracite coals are used in the raw state. There are good reasons for the belief that all coals could be used raw, with a proper construction and management of the blast furnace.

The third marked epoch in the iron manufacture originated in the introduction of the hot blast. The great effect of the *hot*, as compared with the *cold* blast, in economizing fuel, has been generally ascribed to the absence of the cooling action of the cold blast on the combustion. This is the opinion maintained by Dr. Thomson in his report to the British Association, by Dr. Clark in a Paper read before the Edinburgh Society, and by the late Mr. Mushet in his Papers on Iron and Steel.

There are reasons that make this explanation rather doubtful. Mr. Truran ascribed the economical superiority of the hot blast to two separate causes:—"The first is, that the heat thrown into the furnace along with the blast, permits a corresponding quantity of coal to be withdrawn from the burden of materials, and a proportionate reduction in the volume of blast. The effect is seen in the augmentation of make, but not in any saving of fuel. The second cause is, that the reduced volume of blast, and the large amount of heat which it carries with it, cause a diminished consumption of fuel in the upper parts of the furnace, the result being that a quantity of fuel is saved at the furnace greater than what would be due merely to the caloric introduced by the blast." The precise action of the hot blast does not seem as yet to have been thoroughly investigated. It is well known that a blast furnace works better in winter than in summer, on account of the less quantity of aqueous vapour contained in the atmosphere in cold weather; it is not improbable that heating the air may have an *indirect* tendency, under certain circumstances, to deprive it of its moisture.

The credit of the invention of the hot blast is, as is well-known, due to Mr. J. B. Neilson, of Glasgow, who, in 1828, took out a patent for the plan. (Specification, No. 5701, Old Law.) The benefits of this discovery were greatly felt in Scotland; the coals of that country being generally unfit for coking; losing, in fact, 55 per cent. in the process. By using the hot blast, the coal could be sent in its raw state to the blast furnace, and a saving of one-third of the fuel was the result. The hot air seems to have a purifying influence on the coal, rendering less necessary the process of coking, and making inferior coals more available in the manufacture of iron.

We have thus an unlimited supply of fuel, of ore, and of flux, with no want of manufacturing capital and energy to second these resources of nature. The result is a manufacture transcending in extent everything else of the kind in any other time or country. But there is also an unlimited competition; and, unfortunately, quality is too often overlooked in the race after quantity. The immense impetus given to the make of malleable iron, by its demand for the war and mercantile navies of the world, has raised the demand for good qualities of iron. For iron ships of war, good iron is a question of life and death—of victory or defeat. Our iron-masters would do well to reflect on the possibility of the Government taking the manufacture of armour-plating it requires into its own hands, in case the quality of English iron continues to lag so far behind its quantity. They would also do well to remember the course that the Federal Government found itself obliged to take with regard to the production of iron for naval purposes. We may never know to what extent the late repulse of the Federal gunboats before Charleston was due to the bad quality of the iron armour plates. Last year, however, the American Government gave out, as a result of its own experience, its determination to be independent of the private dockyards and ironworks. The intention of that Government is to manufacture itself all the iron that is needed for the construction of our iron navy.

---

[*] See Mr. Woodcroft's Abridgements of Specifications relating to the Manufacture of Iron and Steel, 1858.

Having thus briefly traced the quantitative progression of the iron manufacture, we will take occasion to offer a few observations on what may be termed the quantitative retrogression in the make of iron.

ENGINEERS AFLOAT.

THE following is a statement of the disabilities under which the Royal Naval Engineers consider they labour, and of the means they deem necessary to place them on a more satisfactory footing than they at present occupy in Her Majesty's Service:—

1st. That the pay of naval engineers is insufficient, and that an increase of pay in their case would be a measure not only of justice but of wise economy. Of justice, because with their present rates of pay they are unable to maintain the position their rank in the service demands, and also because the other officers of the civil branch, of equal rank, are better paid for services which the engineers consider are neither more responsible nor arduous than their own. And of a wise economy, because by increasing the pay the Admiralty would then be able to secure the best of the engineering talent of the country for the Royal Navy, and as the duties and responsibilities of the engineers are daily increasing in consequence of the various additions and alterations to the mechanical arrangements of ships generally, so also is the necessity for increased skill and intelligence on the part of the engineers.

2nd. That naval engineers be permitted to retire at an earlier age than at present allowed, with an addition to the rate of half-pay to which they may be entitled. The request for retirement is submitted on the consideration, that from the peculiar and trying nature of an engineer's duties, his constitution receives injury, and as a rule it will be found he is physically incapacitated at an earlier age than 60 years for the active discharge of the duties of a chief engineer at sea.

3rd. That the accommodation for assistant-engineers is, as a rule, positively bad; that it would be conducive to the good of the service if they were made gun-room officers; that the senior assistant in all ships should have a cabin, and that when an assistant engineer is in charge he mess in the ward-room. The accommodation generally is so bad that we believe it to be one great cause of disease, and were the assistant-engineers made gun-room officers, we believe it would tend not only to improve those already in the service, but be the means of inducing a superior class of candidates to offer themselves for entry, as well as saving space in the ship. The peculiar duties devolving upon the senior assistant make the want of a cabin more felt by him than by any of the others. Allowing the assistant engineer in charge of the machinery to mess in the ward-room would be beneficial to the service, by placing him in close communication with the other heads of departments in the ship, and materially strengthen his position in the execution of his duty.

4th. That assistant engineers, after serving the prescribed period, and having passed either a provisional or other examination, receive the pay of the next higher class; that after becoming commissioned officers they be allowed a scale of half-pay; and that all time served from date of entry count for full and half-pay; their names also to appear in the Navy List on becoming commissioned officers. Under the present system, the assistant engineer, after serving the stipulated period, and passing his examination for a higher class, is kept waiting for his promotion, generally for a long and indefinite period, which we think ought not to be the case.

5th. That the widows of engineers be granted ordinary pensions. They feel convinced that this measure is one of great moment to the junior branches of the class; the nature of an engineer's duties frequently impairing or destroying the health of the most robust before they attain the position of chief engineer.

6th. That a distinct rate of half-pay be granted to inspectors of machinery afloat, according to their rank, and that full and half-pay, both of inspectors of machinery and chief engineers, be allowed to increase at a proportionate rate for each year's full-pay service, as the present system of requiring five years' service to be completed, for an increase of full and half-pay, is productive of great hardship to those officers who, from illness or inability to procure employment, fall short (possibly by only a few months) of the required time, and thereby lose the advantage of their service, during the remainder of the interval.

7th. The engineers of the Royal Navy, viewing with satisfaction the course pursued from time to time by their lordships in appointing naval engineers to fill vacancies in the various dockyards, trust the practice will be continued, as they are convinced such a course has been, and will be, productive of much good, and benefit the public service.

NAVAL ARCHITECTURE.

THE following is a brief abstract of a Paper "On the Naval Architecture of the Exhibition of 1862," contributed by Admiral Paris, C.B.:—

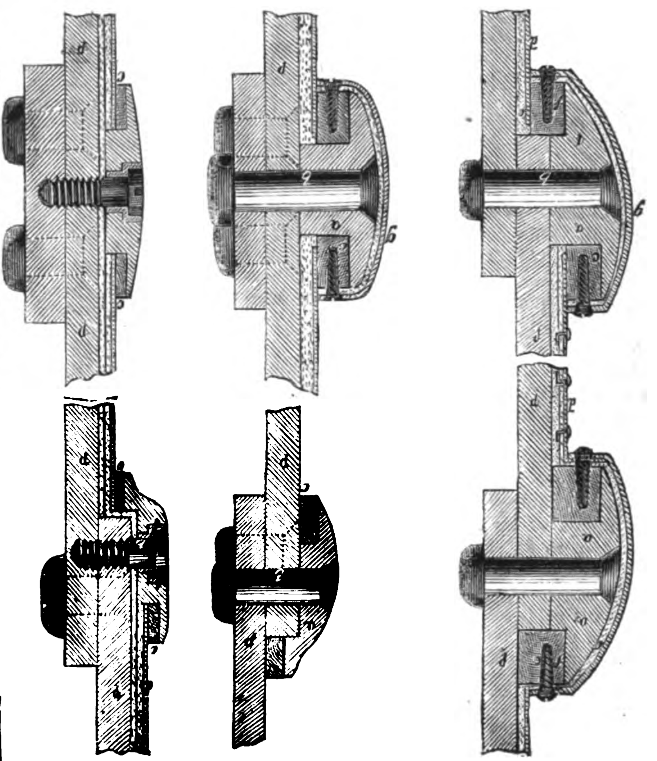
The author began by referring to those terrible guns which were in the main gallery of the Exhibition, and after speaking of the perfect mechanism displayed in their manufacture, went on to consider the purposes for which they were made, and thus came to the models of men-of-war, representing Naval Architecture as it was, as it is, and, for some little time at least, as it will be. Although, after leaving the artillery in all their reality, it seemed almost a disappointment to have to view our war ships on so small a scale, yet they represented the greatest revolution of the greatest art of man, and showed the long train of attempts and labours through which the actual maritime generation had passed; for sailors not yet old have had to contribute towards forming four quite complete and different navies during the last forty years. The most curious and complete collection the author stated was the one exhibited by the English Admiralty, who had conceived the happy idea of representing a succinct history of Naval Construction since the building of the "Great Harry," in 1488. The great difference between the style of architecture of that day and the present was spoken of, and science was charged with having deprived the art of its elegance, while she had given to it qualities which were better suited to it, and which had rendered our modern vessels more like real ships of war The model of the "Howe," three-decker, was referred to, and after speaking of many good qualities which ships of her class possessed, and of the regret with which every old sailor saw those noble vessels superseded, the author stated that that class of vessel served to represent the first of the four periods of history illustrated by the Admiralty models. Paddle-wheel steamers were next mentioned, and although their introduction did not lead to any material changes, from the fact that their paddle-boxes occupied the most valuable part of the vessel's battery, yet they served to represent the second period in the history illustrated by the Admiralty models. The screw-propeller showed the third and most important period, since it allowed us to unite in one vessel all the qualities of a sailing-ship and steamer, without diminishing its military power, and at the cost only of a part of of the provisions and water. There were many difficulties, however, to be overcome before the screw could be applied as was desired, but these were surmounted in the first instance by M. Dupuy de Lôme, who caused the "Napoleon" to carry her ninety guns at a speed of 12 knots; and unless there came some other unexpected discovery, M. Dupuy de Lôme seemed to have produced the type of vessel destined to command the sea, and, in time, to be substituted for every other. But the introduction of terrible explosive shells soon showed that wooden vessels unprotected were entirely unfit to cope with them, and the author referred to the battle of Sinope as an illustration of this, and stated that solid shot could not have destroyed the Turkish fleet in anything like the short time in which the shells effected its destruction. This, then, he said, brought to our consideration the iron-plated ships, and with them opened the fourth and last period of the history of Naval Architecture as was set forth in the Admiralty department of the Exhibition. The author again mentioned M. Dupuy de Lôme as being the first to embody all the requisite qualities for a really good sea-going iron-plated ship in the "Gloire," and regretted that her model was not exhibited at the Exhibition. He considered the loss of guns, which must be a condition in the application of heavy armour to ships, to be adequately met by the invulnerability obtained in the ship. After dwelling upon the qualities most desirable in vessels of this description, the author came to the question of cost, and showed that it was the result of our increased command over our vessels which had led to the enormous increase of expense; since with the engine and screw we could drive a vessel of almost unlimited dimensions, while in our old sailing ships any material increase was impracticable from the inability to work the sails efficiently. With regard to the question whether it was most desirable we should have high speed and partial protection, or more perfect protection at the cost of speed, the author stated that too little consideration for perfect protection had caused alterations in ships which, although they may cause them to be better vessels in a heavy sea, would, at the time of fighting, deprive them of very many advantages of greater value. Reference was also made to a model of a cupola ship, and the author considered that the American war had demonstrated its utility in smooth water rivers, but that great doubts remained as to whether such vessels could be made sea-worthy; here he referred to the fact, that most inventions appeared to be of a defensive character only, and spoke of the many forms designed for glancing shot, with low, inclined sides and other similar contrivances, as so many utter failures, without a nautical quality worthy of notice. He next treated of vessels being used as *Rams*, and upon this subject, stated that a distinguished French officer advocated the use of the "prow" in the first book ever published on the screw-propeller, in 1843. As to which may be considered the victor up to the present time—the gun or the iron plate—the author considered that, with every chance of error in the aim, and taking into account wasted or oblique shot, the protection may be looked upon as inferior. The probable behaviour of our heavy iron-plated ships at sea was then treated of, and the author pointed out the great necessity for a proper distribution and adjustment of the weights, which now became a matter for more than ordinary care, seeing that the vessel's sides are so burdened. After some observations upon the question of rolling, the author suggested that certain sections of a vessel should be taken and dealt with separately, with a view of ascertaining the influences of each; and asked if experiments could not be made, to ascertain the influence of the inertia of the weights, and expressed by diagrams. In conclusion, he stated that a wide horizon of useful information existed, although as yet it was very obscure, and he believed the Institution of Naval Architects to be one specially adapted to throw light upon it, and to hasten in every way the advancement of naval science.

PRESERVING WOOD WITH PYROLIGNEOUS ACID.

From reliable experiments that have been made in Europe and the East Indies with railway sleepers which had been treated with pyroligneous acid, it has been demonstrated (says an American paper) that they endure three times longer than the same kind of timber, not so prepared, when exposed to similar influences. Many improvements that have originated in America have been first applied in other countries. This has been the case with respect to the treatment of timber with pyroligneous acid. Its application for such purposes was proposed in New York forty years ago, but it has not yet come into general use there, while it is in very common use in England. In the New York *Daily Advertiser*, of Dec. 24, 1823, a description was given of experiments that had been made in treating timber with pyroligneous acid, and its benefits and modes of application were clearly described. No railroads were then in existence; consequently, its use was chiefly urged for ship timber exposed to rapid decay. The article on the subject said:—"When seasoned timber or planks are hewn into the intended shape,'put them under cover for a week or ten days to protect them from the rain. During this time let the acid be applied to the surface daily with a bursh. It will penetrate an inch or more into the wood and will be found an effectual preservative. The central part of the wood or heart of the oak being less liable to decomposition, it will require less of the acid. The frame of the ship or boat may be put together when all the external parts of the timber are completely saturated. Green timber cut in thick forests after being saturated with this acid will be nearly as good for ships, steam and canal boats, as the teak wood of the East Indies or the live oak of our sea-soasts."

The pyroligneous acid recommended for this purpose was the condensed smoke of wood. The best way to obtain it is by the distillation of wood in an iron retort and the condensation of its vapour in a refrigerator. The charcoal thus obtained in a retort is of excellent quality for smelting iron, and the crude pyroligneous acid may be applied without any further treatment to the timber. It was not only recommended for ships' timber to prevent dry-rot, but also for the timber of gun carriages, posts set in the ground, the sills of wooden buildings, &c. By smoking timber in the same manner that hams are smoked, similar results are obtained, for the preservative agent is the creosote in the fluid and the smoke. In coal tar there is a similar preservative agent called carbolic acid, which in many of its properties resembles creosote. It answers the same purposes as an antiseptic for timber, and is used for this object, but it is disagreeable to apply; wherever it can be obtained conveniently, however, no better substance can be applied to timber intended to be exposed to moisture and the weather, more especially when in contact with the ground.

GRIFFITHS' METHOD OF SHEATHING IRON SHIPS.



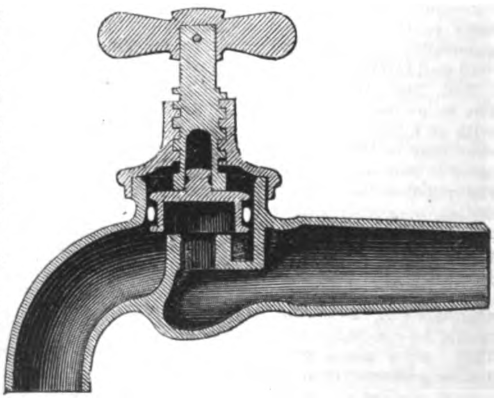
Section No. 1.

Mr. R. Griffiths, of Mornington-road, the well-known inventor of the "Griffiths' Propeller," has recently protected an invention for sheathing iron ships with copper to keep them from fouling. The engravings represent in section several methods of securing the sheathing. *a*, *a*, in the several sections shown, are strips or bars of iron or other metal secured by screws, bolts, or rivets *b*, *b*, along the longitudinal joints of the plates forming the shell of an iron ship. The application of the strips or bars *a*, *a*, to the longitudinal joints of iron ships has the effect of imparting great additional strength to the sides of such vessels, and also of protecting the heads of the rivets and joints which are covered thereby. The sectional form of the strips also affords the means by which the longitudinal joints of iron ships are effectually caulked and prevented from leaking, as shown by the upper part of section No. 1.

In place of the ordinary elastic caulking being employed for filling up the grooves formed by the strips, they may be filled with strips of metal, such as zinc, lead, or alloys of soft metal. The strips may either be fixed over the longitudinal joints when constructing iron ships by part of the bolts or rivets forming the joints passing through the bars *a*, *a*, and the plates *p*, *p*, of the ship, or they may be fixed over the longitudinal joints of vessels already constructed by rivets placed at an angle between the rivets forming such joints. Rabbets or recesses are formed between the inner surface of the bars *a*, *a*, and the iron plates *p*, *p*, of the vessel, into which strips of wood or other suitable caulking material *c*, *c*, is inserted for the purpose of making a secure joint, and also for the purpose, when required, of fixing and securing the edges of the metallic sheathing. A coating of marine glue, bitumen, Trinidad pitch, or other suitable adhesive non-conducting material *e*, *e*, is laid over the surface of that portion of the iron ship or vessel to be sheathed of sufficient thickness to thoroughly insulate the iron plates *p*, *p*, from contact with the sheathing metal *d*, *d*, when fixed thereon, the surface of the iron being first well cleaned and "payed" over with a solution of Trinidad pitch or other bituminous or adhesive material dissolved in naptha, petroleum, or other spirit. The surface of the vessel to be sheathed having been coated or covered, the inner surface of the sheets of sheathing metal *d*, *d*, are coated with prepared canvas, felt, or other fabric; and in order to secure it more firmly thereto, small nails may be driven through the sheathing and clinched at the back of the prepared canvas. The sheets of sheathing metal *d*, *d*, thus prepared, are then applied to the prepared surface of the vessel to be sheathed, heat or other means being employed to cause the two prepared surfaces to adhere firmly together. In some cases the horizontal edges of the sheathing metal simply pass into the grooves or recesses formed by the bars *a*, *a*, being held securely by the wood or other filling *c*, *c*; in other cases the edges of the sheathing metal are turned up at right angles and secured, as shown, to the wood by screws or nails, or by the screws *f*, *f*, which secure the caps *g*, *g*, of sheathing metal, which cover and protect the bars *a*, *a*, such caps or covers *g*, *g*, being readily removed at any time for examination or repair if required. The caps *g*, which cover the bars *a*, *a*, are made of stronger metal than the sheets of sheathing metal, as they serve as protectors to the sheathing from the injurious action of chain cables or other rubbing surfaces. The vertical joints of the sheathing metal are made secure by riveting strips of metal along the vertical edge of one of the sheets, and then inserting the edge of the adjoining sheet between the strip and the sheet of sheathing to which it is fixed.

KENNEDY'S IMPROVEMENT IN TAPS.

Mr. T. Kennedy, of Kilmarnock, N.B., has obtained a patent for the following invention in taps. The accompanying engraving illustrates a tap embodying the improvements. A cylindrical chamber is formed in a convenient position on the tap pipe or body, and within this chamber there is formed a valve seat, the opening or openings of which communicate with the inlet end of the tap, whilst the outlet end of the tap communicates with a convenient part of the chamber outside of the valve seat. The closing detail consists of a kind of piston or plunger formed with a recess, in which there is fitted a disc or piece of an elastic



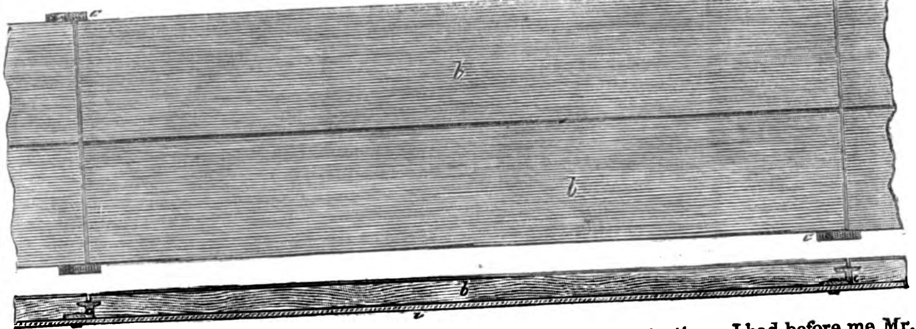
material, such as vulcanized rubber, and the closing detail is pressed against the valve by means of a screw spindle. The closing detail is connected loosely to the screw spindle, but so that the latter can draw it off the valve seat when the pressure is not sufficiently great to do so on the screw spindle being drawn out. The screw spindle works in a nut screw tapped in a cover, screwed or otherwise fixed to the top of the valve chamber. To prevent leakage through this cover a rolling packing is applied to the closing detail or piston, such rolling packing consisting of a ring of elastic material, such as vulcanized rubber. The packing ring is retained between flanges formed on the closing detail or piston, but these flanges are as much further apart than the thickness of the packing ring as will permit its necessary rolling movement. The inside of the chamber is turned smooth for the rolling packing to work upon, and if vulcanized rubber is used, the surfaces of the tap with which that material comes in contact are, by preference, tinned when such parts are formed of brass or other metal to which vulcanized rubber tends to adhere.

IMPROVED METAL SHEATHING FOR IRON SHIPS.

The following is a description of a plan for sheathing iron ships with wood and metal, recently proposed by Mr. W. Mulley, of Plymouth:—On the skin of the ship iron holdfasts *c*, are riveted. The holdfasts may be of any desired length, so as to secure two or more planks of wood *b*, as shown in the accompanying engravings.

The method to be adopted in carrying out the work is to begin by fastening one of the irons anywhere, say on the side amidships, between the lap-plates, then show the second iron its berth, and cut the sheathing off the exact length required, and quantity in breadth equal to the length of the iron; form the ends to correspond with the iron; when so fitted take them out again, and introduce bitumen, or whatever composition is to be used, and replace them; then bring the second iron to its berth, and fasten it, always with the flange outwards, and so on throughout. In parts such as the bows, quarters, and turn of bilge, the sheathing might vary both in length and breadth. The whole should be well caulked, thickly coated with pitch and tar, and be ready for felt and metal the same as an entire wood-bottom ship. Every part of the ship, including rudder, could be sheathed with equal facility—the metal braces brought outside of all, provision being made for the metal bolts passing through the iron sternpost, &c. The sheathing and iron holdfasts are of minimum dimensions.

MULLEY'S METAL SHEATHING FOR IRON SHIPS.



THE HYDROTESTOMETER.

At the last general meeting of the Institute of Naval Architects, Mr. Thomas M. Gladstone, C.E., Assoc.I.N.A., read a Paper "On the Hydrotestometer, or an Instrument to determine the Strain on a Ship's Cable when riding thereby, under all Conditions of Weather, and for other Purposes."

The author first observed that it had long been a matter for much observation to ascertain exactly what amount of strain a vessel puts upon her cable under various conditions and circumstances, and hence, he presumed, the subject would be one of interest to the Institution of Naval Architects. Hitherto, the proper strength and proportions of cables, &c., had been regulated by no really scientific data, and therefore if by suitable and convenient machinery such data could be accurately obtained, much good would be the result, since economy would be promoted, and greater security given to both life and property exposed to the dangers of the sea. From evidence given before a Select Committee of the House of Commons, in 1860, it was proved that the chain cables and anchors in the merchant service were in a most unsatisfactory and even untrustworthy condition, save in vessels of leading ship-owners, and those of large steamboat companies, and this it was that first drew the author's serious attention to the subject, and gave rise to those labours which have resulted in the "hydrotestometer." The plan of this instrument was submitted to Admiral Robinson, the Controller of the Navy, who received it so cordially that the author was induced to request of the Admiralty the co-operation of the Commodore and Master Shipwright of Woolwich Yard, and this request being granted, the whole merits of the instrument were fully discussed by those officers, and reported upon accordingly. After reading a report which he forwarded to the Admiralty, accompanying the one forwarded by the officers above referred to, the author stated that the want of scientific knowledge which the hydrotestometer is calculated to supply, delayed for twenty years the introduction of iron cables into the Royal Navy, so that the great economy effected by their use was also for that long period delayed. The "hydrotestometer" is on the principle of the hydraulic ram, and a drawing of one, which will measure a pressure of 200 tons, was shown. The instrument occupies but a small space, being 6 ft. long, 3 ft. broad, and 2 ft. high, and may be placed in any convenient position. It has a bridle attached to it, and a stopper to grasp the chain cable, so that the whole strain shall come directly upon the instrument; and the pressure or strain is at all times indicated by a pointer and dial attached for the purpose. He proposed that two of these instruments should be placed on board of two separate vessels of each class, the whole cost of which would be about £2,000, and he added that, when not in use for the special purpose for which they were designed, they might be employed in various useful ways, and from their capability of recording the smallest pressure, valuable results might be obtained. He desired that the instruments should be fully criticized, and a fair and impartial opinion passed upon it, since his desire was to render our knowledge of the strain exerted upon cables just as exact as it is upon the force of the wind and tide, and he believed that such information would give to the shipbuilder clearer views upon the qualities of his models, and tend to perfect the lines of every ship built in the future.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

At the annual meeting of this society, April 21, 1863—E. W. Binney, F.R.S., F.G.S., President, in the chair—Mr. Leopold Hartley Grindon was elected an ordinary member of the society.

The following reply to Dr. Rankine's Paper, read at the last meeting, was communicated by Mr. Dyer:—

In Dr. Rankine's Paper, entitled, "Note on Two Events in the History of Steam Navigation," he calls attention to my Paper, "On the Introduction of Steam Navigation," and expresses regret that "the author has noted, either very slightly, or not at all, an event of paramount importance:—The first adaptation of the double-acting cranked steam engine to drive a paddle-wheel." Now, I own to have taken no notice at all of this double-cranked motion, simply because I did *not* consider it of much importance in attaining success in *steam navigation*. I had before me Mr. Woodcroft's interesting treatise, and I fully appreciated his advocacy of the claims of Mr. Symington for having "fitted up the 'Charlotte Dundas,' as the first practical steamboat, in 1801." This *fact* is fairly stated in my Paper.

I aimed to place before the society the several inventions and discoveries relating to the use of *steam power* to supersede that of wind to navigate vessels, and to prove that the final *success* was due to *Watt's steam* engine. No great stress need be laid on the double cranked action, or on any of the other methods used for *transmitting* the power to the paddle wheels. The principles involved in overcoming the resisting forces by steam power in navigation, are entirely apart from those relating to the mechanical means of converting rectilinear into circular motion. It seems strange that such able engineers as Dr. Rankine and Mr. Woodcroft should have given this prominence to the said double-crank action. Whatever may have been the degree of success in the case of the "Charlotte Dundas" in 1801, and whatever may be said about the bar to further progress of Symington's inventions by the *Duke's death*, the fact remains clear that his schemes died out with the Duke, as no more was heard of them after the "Charlotte Dundas," and from some cause, she was discontinued; and it was, in fact, fifteen years after her advent before the "Margery" came out from the same waters to enter the Thames, in 1816. What shall be said of the "enlightened" of Glasgow, if "Symington's practical steamboat" was suffered to rot and be forgotten, leaving no successor, and the inventor himself to remain unrewarded and unnoticed for fifteen long years?

Through the limited space allowed for the abstract of my Paper, Dr. Rankine was misled respecting the other *event*, also cited by him from Mr. Woodcroft's book—namely, that I had "passed over the first introduction of steam navigation into Europe, by Henry Bell, in 1812;" for in my Paper due notice is taken of this well-known experiment of Mr. Bell. Although his trial boat proved a failure, on account of its being a very small one, and of his want of pecuniary means for continuing or extending the experiment, and the lack of any aid or encouragement afforded him by others, yet his trial boat served as the model for constructing the "Margery," three years after, which, as I have before said, was a success, and the first steamboat on English waters. I, therefore, think that due honour should be paid to the name of Henry Bell, for his spirit and enterprize, and a due stigma cast upon the capitalists who allowed him to sink under pecuniary pressure, from which he ought to have been relieved by them in so important an enterprize.

Mr. Rawlinson, C.E., has been sent into Lancashire and Cheshire by the Government to report as to the requirements and capabilities of the neighbourhood, in the way of works of public improvement.

The Commissioners of Sewers, at their weekly meeting in the Guildhall, on Tuesday, decided not to proceed in opposing the railway bridge innovation at Ludgate-hill, as they did not think it wise to spend the ratepayers' money in so doing.

REPORT OF THE ORDNANCE COMMITTEE ON RIFLING SMALL ARMS.

The report of the Ordnance Select Committee on the various systems of rifling small arms has just been printed. The systems which were taken into consideration were what is known as the Enfield principle, viz., three or five broad shallow grooves, either of uniform or progressive depths; the Lancaster oval bore, with increasing spiral—the above in two calibres; the Whitworth hexagonal bore, with quick twist; and Mr. Westley Richards' systems of breech-loading applied to an octagonal bore—the two last in the smaller calibre only. In proceeding to determine the respective merits of the large-bore rifles, the five-grooved Enfield was first placed in competition with the Enfield service rifle, which, in all other respects, it resembles. As the width of the grooves is the same in both cases, it follows that the surface of the lands is considerably reduced in the five-grooved rifle; and the results obtained show that this alteration gives a decided advantage in precision. It appears that the question of increasing the number of grooves, or rather of reducing the amount of frictional surface presented by the broad lands of the service Enfield by running a narrow groove down each of the lands, has for some time been entertained by Mr. Boucher, the object being to increase precision by a tighter-fitting bullet, without sacrificing facility in loading. Two Enfields, constructed on this plan, were tried with two kinds of ammunition, viz., a disc bullet, and a polygonal-sided bullet, with cavity at base. The shooting was wild, however, and Mr. Boucher withdrew the disc bullet, preparing, however, for further trial with polygonal bullets of somewhat less diameter, and a slower burning powder than that used in the service. As the nature of the proposed experiments would have involved a long and laborious investigation, the committee decided that the suggestion should form the subject of a future and separate inquiry.

The five-grooved Enfield was next placed in competition with another, differing from it only in having the spiral increased to one turn in 63 inches. This increase of pitch led to improved precision at all ranges, but more especially at the longer ranges. The quicker twist has, however, the disadvantage of increasing the tendency to foul. Two five-grooved Enfields, both with one turn in 48 in., but one having a barrel heavier by four ounces than the other, with a corresponding diminution of weight in the stock, were next tried, when a very slight superiority in precision was found on the part of the heavier barrel. The latter was, therefore, selected for comparison with the five-grooved arm with a spiral of one turn in 63 inches, the result being that, in fair weather, the slower pitch was found sufficient for all ranges up to 1,000 yards. In boisterous weather, and at the extreme range of 1,200 yards, the results were in favour of the quicker twist. The committee were, therefore, led to give the preference to this rifle above the other varieties of Enfield arms submitted for trial.

The large-bore rifles on the Lancaster principle were of a calibre adapted to the service 0·55 ammunition, having an elliptical bore, and a spiral of one turn in 36 in. at breech, increasing to one in 33 in. at muzzle. The results obtained by the trial of this arm, in comparison with the Enfields, show that the sharp pitch adopted by Mr. Lancaster has the advantage in precision at all ranges above 500 yards, and that at 300 yards the precision of both rifles is about equal. The committee next proceeded to test the Lancaster rifles for precision after they had to a certain extent been fouled and exposed to the weather for several days, when it was found that the precision of these arms is not deteriorated by continued firing, while that of the Enfield is. An objection has been frequently raised against the Lancaster system on the ground of its supposed liability to lose its elliptical form through the unequal friction exerted in forcing the bullet into its larger axis; but the committee are satisfied, from their own experience, that the alleged defect, if it exists at all, is so inconsiderable as to be of little or no importance. It has likewise been urged that freeing at the breech, as in the Lancaster rifle, is a disadvantage, as the bullet has to undergo a certain amount of distortion in its passage through the narrower part of the barrel. The committee think that this distortion must at least equally occur in any rifle where the depth of the grooves is progressive, as in the Enfield; and they consider that an advantage may be derived from both freeing at the breech in one system, and progressive growing in the other, in cases where the expansion of the bullet has not been completed at the first moment of discharge. Reference to the experiments at Woolwich and Hythe, in 1853-54, shows that the freed breech was then considered to have the advantage of diminishing the liability of the bullet to slip. The same may be said of Mr. Lancaster's increasing spiral; and the results of all the experiments with the large-bore rifles show that in the Lancaster there is now no greater tendency of the bullet to slip than is common to most systems of rifling. Having carefully considered the relative advantages of the Enfield and Lancaster systems applied to large calibres, and adapted to the same ammunition, the committee came to the conclusion that the Lancaster has the advantage, both as regards precision when foul, non-tendency to accumulate fouling, simplicity of management (a smooth barrel being more easy to clean than a grooved one), initial velocity, and trajectory. As regards penetration, rapidity of fire, and cost of manufacture, the two rifles are about equal.

The committee next proceeded to a trial of the small-bore rifles, all of which exceed the service Enfields in weight of barrel, which excess is got rid of partially, and in the Enfield Whitworth entirely, by reducing the weight of the stock. It was held essential, in determining the fitness of any arm for military service, that it should retain its precision with that lubricant which has been proved by experience to be the best adapted to all climates and condition, viz., pure bees' wax. With a view to meet this condition, Mr. Whitworth submitted an ammunition in which the grease pellet was covered with a thin coat of wax, a combination which, in the opinion of the committee, failed to fulfil the requirements which render pure wax necessary; and, with a view to test the fitness of the service lubricant for small-bore rifles, experiments were made with wax pellets. With these the shooting of both the Whitworth and Enfield rifles was found to deteriorate, while that of the Lancaster rifle improved to a degree which rendered its shooting not only superior, but equal to that of the Whitworth and Enfield when fired with the grease lubricant. The precision of Mr. Westley Richards' breech-loading rifle was not affected by the employment of wax on the bullet. From these results it would appear that the wax lubricant in this form suits the Lancaster rifle, but the committee are inclined to think that its success is due rather to the fact that it acts as a wad than as a lubricant; and in this opinion they are borne out by Mr. Lancaster himself, who advocates the employment of a felt or other wad as being conducive to the attainment of the highest precision with rifles on his principle. It does not follow, however, that wax would be found suitable in a small calibre if applied on the bullet, as in the present service cartridges, as the bullet would have to be reduced in diameter to render loading possible under such circumstances.

In the experiments made with this lubricant it was observed that the Enfield and Lancaster rifles had a tendency to lead, and the loading, more especially with the former, was occasionally performed with difficulty. As this was not the case with the Whitworth rifle, the committee thought that a severe trial for fouling with this lubricant would be well calculated to bring out the relative advantages or disadvantages of the different systems of rifling, and with this view they decided to fire 1,000 rounds lubricated with wax from each of the small bores. The Enfield commenced to load with difficulty at the seventh round, which increased as the firing proceeded, the bullet on most occasions having to be forced through the paper, and at the 93rd and 606th rounds respectively the bullet jammed in the barrel, and had to be driven home by blows from a mallet. In the Lancaster rifle the loading was comparatively easy, although on some occasions unusual force was required to drive the bullet down the barrel. In the Whitworth rifle the loading from first to last was so easy as to require no greater pressure than the weight of the ramrod.

From the data obtained by these experiments, the committee arrived at the conclusion that the present Enfield rifle, 0·577 bore, is not constructed on the best possible principle of rifling. With its present twist, it fails in precision at distances above 600 yards, and any attempt at improvement by increasing the spiral entails a tendency to foul, and thus mars its efficiency as a military weapon. Another defect in this system is the large frictional surface which the broad lands present to the descending bullet, rendering a comparatively large windage necessary to secure easy loading. In the elliptical and polygonal systems the frictional surface is considerably reduced. In the Whitworth hexagonal bore, the resistance to the bullet is practically less than the ellipse, for, as the bearing surfaces in the polygon are perfectly flat, the bearing on each is a minimum, and the bullet in its passage down the barrel is exposed to pressure over a less portion of its circumference than is the case in the ellipse, where the surfaces incline to coincidence. In the course of the experiments, the Enfield and Lancaster principles have been tested in both large and small calibres, but Mr. Whitworth's polygonal system has been confined to small-bores; not that it is inapplicable to large-bores, or incapable of giving proportionately good results, but that, as with the weight of bullet and charge now adopted in the service, superior results are obtained by the reduced bore, Mr. Whitworth has expressed his unwillingness to employ an inferior construction when better proportions are available.

The committee are of opinion that, as the present system of musketry instruction is calculated to produce a very high standard of shooting in the army, the introduction of a weapon of great precision at long ranges would materially increase the efficiency of the infantry, and place it in a better position to keep down the fire of rifled artillery. But although the reduced bore has shown a great superiority in precision over the large calibre, and in some respect exhibited a greater suitability for military use, yet the wear that takes place in the percussioning is so considerable that the rifle in a very short time is rendered unserviceable. As regards ammunition, the committee think that the Whitworth cartridge is inadmissible for general use, and that, if a cartridge were constructed on the same form as the present service cartridge to suit the reduced calibre, its increased length would render it liable to break in the pouch, and it would be inconvenient to load with. The committee have been informed that the cost of the Whitworth rifle, if made of Enfield metal, and manufactured in large numbers, with a barrel 4 oz. heavier than the present service barrel, common bayonet, and iron furniture, would be about 15s. more than that of the service Enfield; but, as the wear is so excessive, the actual cost of its adoption would be much greater. For these reasons, they do not feel warranted in recommending the introduction of a small-bore rifle for the entire army; but they think that a partial employment of arms of such superior precision would be attended with advantage, and is not inexpedient. At the same time they think it only just to Mr. Whitworth to acknowledge the relative superiority of his small-bore rifle over all others of similar calibre that have been under trial. With the exception of the greater wear, and the difficulty of obtaining ammunition suitable both for rifle and for the service, the committee are of opinion that the Whitworth rifle, taking all other points into consideration, is superior to all other arms as yet produced.

The breech-loading rifles of Mr. Westley Richards have shown advantages peculiar to this species of arm; but, setting aside the expediency or otherwise of adopting a breech-loading musket for infantay, the committee consider the cost of the rifle (nine guineas) so excessive, as to preclude its introduction. At the same time they think that, for cavalry, this system of breech-loading, adapted to carbines, offers such advantages as to compensate for any additional expense that may be incurred by their general introduction in that branch of the army. With regard to the relative merits of the Enfield and Lancaster systems when applied to large calibres, a strict but impartial comparison on all points establishes, in the opinion of the committee, the superiority of the latter. Should it be desired to retain the present Enfield calibre, therefore, the committee, in the absence of any data of their own as to the value of the polygonal system applied to this calibre, are of opinion that the adoption of the Lancaster system will be attended with considerable advantages to the service, more especially as it can be accomplished without necessitating any change in the present service ammunition, or increase of the present cost of supply.—*Birmingham Daily Post.*

AMERICAN IRON BRIDGES.*

The great number of timber bridges, in America might be accounted for from the fact, that the first cost of the truss, or superstructure, of a timber bridge of any given span, was generally less than one-half that of an iron bridge of the same strength. Iron had been occasionally employed since 1835, but only within the last ten or twelve years to any extent.

Cast-iron tubular arches, including one of 80 ft. span, were erected from the design of Major Delafield, about the time when similar arches were adopted, by the late M. Polonceau, in the construction of the Pont du Carrousel, over the Seine. Major Delafield's arched ribs were elliptical in section, the transverse vertical axis being about four times the length of the conjugate axis. In 1858, an aqueduct bridge was erected at Washington, by Captain Meigs, in which the two arched ribs were formed of water-pipes, through which the water flowed. The span of this bridge was 200 ft., the rise being 20 ft. The pipes were circular in section, 4 ft. in diameter inside, and 1½ in. thick. This bridge was 28 ft. wide over all, and the roadway was of timber, supported on wrought-iron spandrils. The bridge was tested with the arched ribs filled with water, and with a load of 125 lb. per sq. foot upon the roadway, making the total weight on each rib about 350 tons. The thrust of one half of this weight upon each abutment would be about 470 tons, corresponding to a strain of 2 tons per square inch of sectional area of iron in the pipes. This strain did not include the pressure of the water in the pipes, which were proved to 300 lb. per square inch. These examples were, so far as the author was aware, the only iron arches yet completed in the United States; and with the exception of a few pivot bridges, and one or two ornamental bridges in the Central Park at New York, they comprised nearly all the cast-iron bridges in that country.

There were a small number of plate, or boiler-iron bridges. The first was erected in 1847, in place of a timber bridge, by Mr. Millholland, on the Baltimore and Susquehanna (now the North Central) Railroad. This was 50 ft. span, and the two girders were each 6 ft. deep, the two sides of each being formed of plates ¼ in. thick. Between the sides at the top a timber 12 in. square was bolted as a compression member, and the top was further strengthened by two wrought-iron bars, 5 in. deep by ¾ in. thick, while four similar bars were riveted along the bottom of each girder. The sides were stiffened by stay-bolts, enclosed in cast-iron distance pieces, 12 in. apart from centre to centre. The centre of each girder was placed exactly under the rails, which were spiked to the timber forming the compression member. The breaking strain of the pair of girders was equal to 250 tons of distributed load, and the weight of the bridge was 14 tons. When completed, this bridge was coupled at each end to a railway waggon; and was slung by chains to a temporary timber truss. It was then taken nineteen miles by railway, run exactly over the place it was intended to occupy, the existing timber bridge was cut away, and the girder bridge lowered with the permanent way ready for traffic, the whole operation not having caused an interruption of more than two hours.

Having been long accustomed to trussed timber bridges, American engineers, in adopting iron, naturally employed it in trusses also. But, before describing the various forms of iron truss bridges, the strength of American iron was referred to. It appeared, from a vast number of experiments made by the United States Ordnance Board, that there was but little iron in any American cast guns of a less tensile strength than 11 tons per square inch; and in 1851, the author had himself seen portions cut from 11-inch guns, weighing 6 tons 15 cwt., tested up to 16·14 tons. The transverse breaking strength of a large number of samples of re-melted iron, when reduced to the English standard of a bar 2 in. deep and 1 inch wide, resting on supports 3 ft. apart, varied from 27¾ cwt. to 48·1 cwt., the general strength being 34 cwt. The minimum crushing strength of the irons experimented upon was 37¾ tons and the maximum 77¾ tons. Experiments made by the Franklin Institute twenty-five years ago showed the mean tensile strength of cast iron at the first melting to be 9¼ tons; and the iron now employed by engineers in Philadelphia bore from 7·14 tons to 10·2 tons. In 1858, Mr. Albert Fink tested the iron used in the construction of a large bridge on the Louisville and Nashville Railroad. When the results were reduced to bars 2 in. deep by 1 inch wide, on supports 3 ft. apart, the minimum breaking weight was 29½ cwt., mean 32·68 cwt., maximum 39 cwt. This iron was a mixture of two-fifths cold blast, two-fifths hot blast, and one-fifth scrap. With regard to wrought iron, the experiments made by the United States Board of Ordnance gave a tensile strength varying from 17 tons to 33·3 tons per square inch; and those of the Franklin Institute a mean strength of 26 tons for plate iron. At the present time 27 tons was generally expected of American boiler plate. Other experiments were also quoted to the same effect; and it was remarked that, from what had been stated, American engineers might work up to rather higher strains than were commonly allowed in this country. The high qualities of the best American iron were due to the purity of the ore and of the fuel employed in the manufacture. In bridges of less than 150 ft. span, even when loaded with a weight of 1·34 ton per lineal foot of single line, the strains did not exceed 3·57 tons per square inch on wrought iron in tension, and 4·46 tons per square inch on cast iron in compression.

Of the iron truss bridges that were described, all had certain peculiarities in common, distinguishing them from the trussed structures adopted in this country. In almost every case the compression members of American iron trussed bridges were of cast-iron cylindrical or octagonal pipes. These simply abutted, end to end, against each other; and although means were employed to prevent lateral motion of the ends, flanges and bolts were never introduced for that purpose. Another, and one of the most important peculiarities was the depth of truss—a depth exceeding that employed by English engineers, except in rare instances, as at Chepstow and at Londonderry. American engineers considered a depth of one-eighth for spans of 200 ft. as only moderate; for shorter spans depths of one-seventh and one-sixth were common; and in the case of one bridge of 120 ft. clear span, the depth was 23 ft., or nearly one-fifth of the span. It should, however, be observed that, in some of the American trusses, the arrangement of the tension members was such that, if the depth of the truss were not considerable, the diagonals would be inclined at hardly more than 8 deg. or 10 deg. from the horizontal; in which case a very large quantity of material would be employed, in proportion to the supporting power obtained. No American iron or timber bridges were ballasted; nor had they any floor, only a foot-path of planks. In bridges having the rails at or above the level of the top chords, known in the States as "deck bridges," parapets were seldom employed; and the trusses were often so short a distance apart, that a passenger, on looking out of a carriage window, was unable to discover any support beneath the train. In no bridges of two or more spans were the trusses made continuous over a pier; each span being always treated as a bridge by itself.

One of the earliest iron trusses adopted in the States was a trellis, known as Rider's Bridge. Cast-iron T or angle irons were employed in compression, and wrought-iron bars in tension. These bridges were so slightly proportioned that they occasionally broke down, and the author was not aware that the plan was now adopted in new structures.

A detailed description was then given of the Murphy-Whipple bridge, having a span of 125 ft., with the railway supported on the lower chords. It was for a double line, and there were three trusses, 14 ft. apart, from centre to centre, the strength of the middle one being about one-half greater than that of either of the others. The trusses were 23 ft. deep, or 0·184 of the span. The top chord was formed of cylindrical cast-iron pipes, and the bottom chord of a chain of square bars, 10 ft. 5 in. in length between the centres of the eyes. Upright cast-iron posts, placed at the same distances apart, divided the truss into panels; and as the posts were in two lengths, they were each trussed by four round rods, to prevent lateral failure. The diagonals were in pairs of square rods, and were formed also as eye-bars, grasping pins 2½ in. diameter in the top chord, where the pipes abutted upon each other, and pins 3½ in. diameter in the bottom chord, thus connecting the links, or bars, of which it was composed. The diagonal tension bars only crossed each other in two panels on each side of the centre of the truss. The top and bottom chords were braced horizontally, with transverse and diagonal bars. The railway bars were supported upon longitudinal timbers, which rested upon transverse wrought-iron rolled beams. The total weight of the superstructure complete was 102½ tons, or 8 cwt. per foot of single line. With an additional distributed load of 3,000 lb. per lineal foot on each line, the tensile strain at the middle tension rods would be 4·27 tons per square inch in the outer trusses; but, with a train on a single line only, the ordinary working strains did not exceed 2½ tons per square inch in tension, nor 3 tons in compression.

In 1861, an iron bridge was erected on the line of the Pennsylvania Central Railroad, across the Schuylkill, at Philadelphia. It had two clear spans of 192 ft. each, and one pivot span, or turning bridge, 192 ft. long. The construction was similar to that just described, but the truss was only 19 ft. deep. The upright posts, or struts, were of wrought iron, so rolled that when two bars were put together they formed an octagonal tube. The top and bottom chords of the turning bridge were of wrought-iron rolled beams, so that either might resist extension or compression. The three spans for a single line contained an average of 5 cwt. of wrought iron, and 7½ cwt. of cast iron per lineal foot. The nett cost of the bridge, exclusive of masonry, was £8,144 10s. or £14 4s. per lineal foot; the wrought iron costing £22 15s. 6d., and the cast iron £6 11s. 3d. per ton.

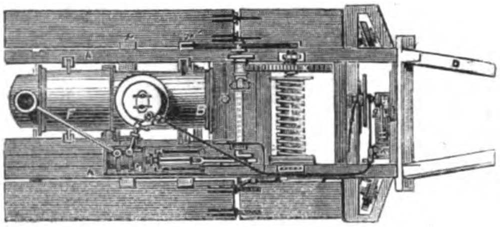
The pivot was of a kind extensively employed for turn-tables. It consisted of a fixed and of a moveable cast-iron disc, both grooved to receive a number of steel rollers, each turned to the frustra of a double cone. A circular railway was laid around the pivot, but the wheels only bore upon it when the bridge was not truly balanced on the rollers. With a load of 14 tons balanced upon one of these bearings, the whole was revolved by a weight of 3½ lbs. hung over a pulley, and connected by a chord to the periphery of the turn-table.

---

* Read before the Institution of Civil Engineers by Mr. Zerah Colburn, on May 5, Mr. Hawkshaw, the president, in the chair.

WRIGHT'S ROTATIVE TRAVELLING CRANE.

FIG. 2



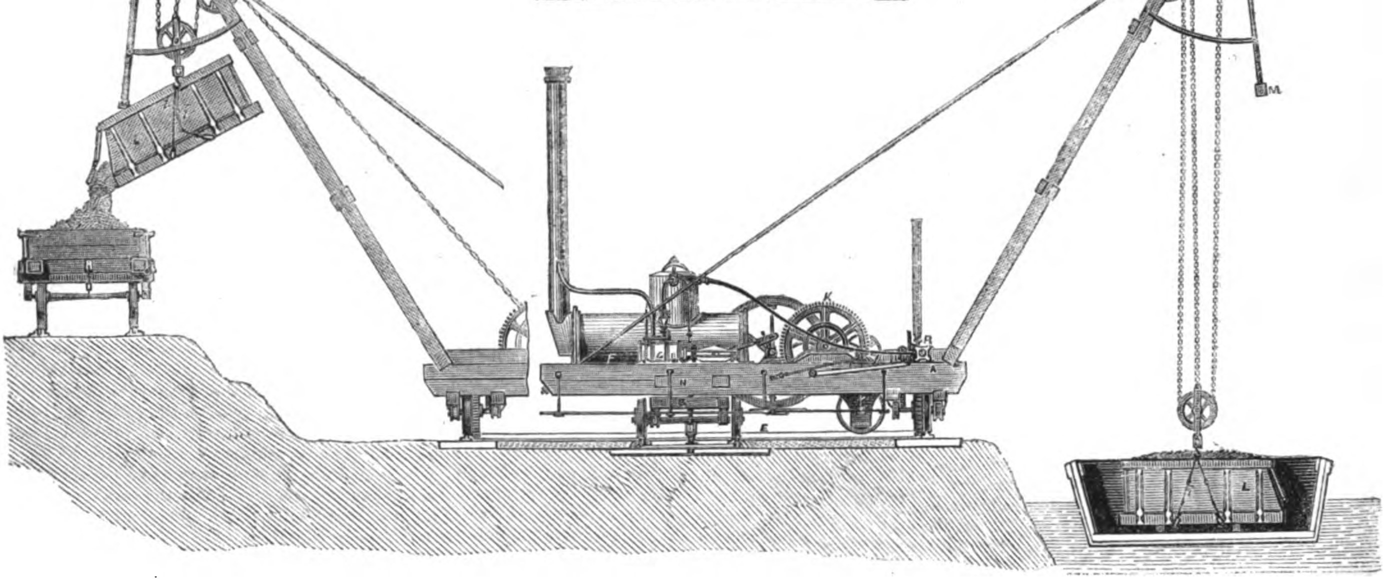


FIG. 1.

The form of truss introduced by Mr. Wendel Bollman was next noticed. In it the load upon each panel was transferred directly to the ends of the truss, through a pair of straight suspension bars, doing duty only in that panel. With the exception of one pair of suspension bars, supporting the centre of the bridge, the bars in each pair were of unequal length, and their lower ends were attached to the upper extremity of a compensating link, in order to allow for contraction and expansion. This bridge could not alter its form under unequal loading. A bridge upon this plan at Harper's Ferry, on the Baltimore and Ohio Railroad, had four parallel trusses for a double line, and a clear span of 124 ft. The span was divided into eight panels, and the depth of the truss was 17 ft. 6 in. The top chords were each formed of a single line of octagonal cast-iron pipes, and the vertical posts were also of cast iron. The strains upon the various parts of the truss, caused by the weight of the bridge and of a load of 1½ ton per lineal foot, were 2·8 tons per square inch in compression in the top chord, and varied from 4·46 tons per square inch in tension in the longer suspension bars to 7·14 tons in the shorter bars. Mr. Bollman had stated, that this bridge was tested with a moving weight of 122 tons of locomotives on one span of single line, or nearly 1 ton per lineal foot, and that the deflection at a speed of 8 miles an hour was 1⅜ in. at the centre.

The iron bridge designed by Mr. Albert Fink had been more extensively adopted than any other on the railways of the United States. In this bridge a pair of diagonal tension bars connected the foot of the principal strut or king-post in each truss, with the ends of the top chord. This pair of diagonal bars supported one-half of the whole weight of the truss and its load. Each half-span was subdivided by a strut, and two diagonal tension bars extended, one to the nearest end of the top chord, and the other to the top of the centre post. Each quarter span was again subdivided into eighths, and these again, for spans greater than 100 feet, into sixteenths. Under the direction of Mr. B. H. Latrobe, then engineer of the Baltimore and Ohio Railroad, in 1852, Mr. Fink erected an iron bridge of three spans, each of 205 ft., where that line crossed the Monongahela river. The depth of the truss was about one-ninth of the span, and the railway was carried at a little above the level of the bottom of the truss. The weight of the bridge, including the permanent way, was only ½ a ton per foot of single line, and, with an additional load of 1 ton per lineal foot, the tensile strains upon the wrought iron did not exceed 5·15 tons per square inch, and the compression on the cast iron 4·25 tons. The Green River and the Barren River bridges were then alluded to, as being nearly identical in construction to that last described.

The Bollman and the Fink trusses for a single line, and in spans of from 160 ft. to 200 ft., cost £14 per lineal foot, or nearly £28 per ton; while timber bridges of the same span only cost from £5 to £7 per foot. Still, iron bridges now met with an amount of favour which appeared certain to insure their ultimate substitution for timber bridges. A gradual preference was being shown to the plate girder, as the great annual range of temperature, from 20 deg. below zero to a reflected heat of 130 deg. in the summer sun, was not favourable to the use of cast iron in structures of such importance as railway bridges.

It was announced that the discussion upon Mr. Colburn's Paper "On American Iron Bridges" would be taken at the next meeting, Tuesday, May 12th, when the following Paper would be read:—"On the Communication between London and Dublin," by Mr. Watson, M.A., Assoc. Inst. C.E.

It was announced from the chair that the President's Annual Conversazione would be held on Tuesday evening, June 2, when the co-operation of members and visitors was requested, in order that a collection of models of engineering construction, and of specimens of works of art, worthy of the Institution, might be made.

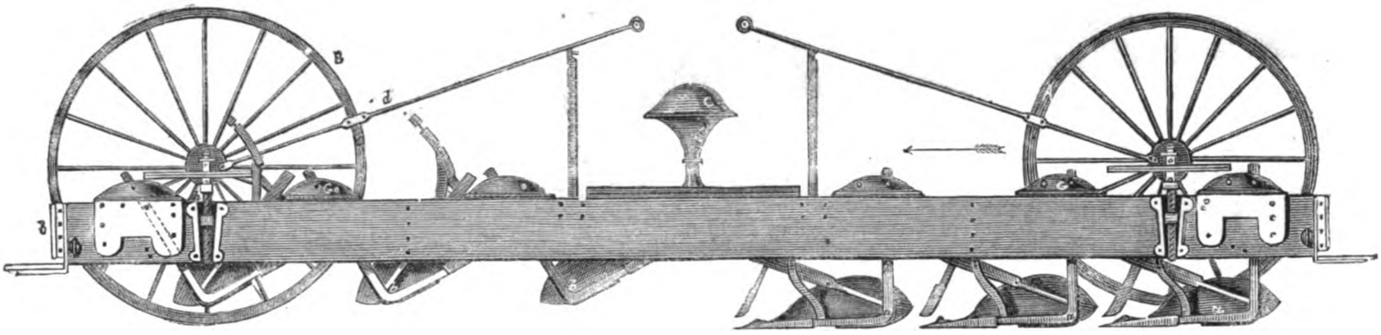
WRIGHT'S ROTATIVE TRAVELLING CRANE.

MR. J. WRIGHT, of Throgmorton-street, has recently patented an improved rotative travelling crane, which is constructed as illustrated in the above engravings.

On a stand or framing of suitable weight and strength an engine and boiler is placed, which, through a pinion on the main shaft, gives motion to a large cog wheel fastened on the spindle of the drum on which is coiled the chain passing from it to the extremity of the jib, and terminating in a hook or its equivalent in the usual manner. A tie-rod passes from the extremity of the jib to the extreme rear of the machine, by which means the weight of the boiler engine and the machinery counterbalances the weight of the substances or materials to be lifted. The whole apparatus turns on a circular rail round a pivot supported on a frame. The operation is as follows:—The chain is made fast to the substance or weight to be lifted, the engine being put in motion coils the chain round the barrel or drum, thereby hoisting the weight. When it has been raised high enough the crane is turned round on the circular rail before mentioned by means of a steam cylinder mounted on the framing, and connected by means of toothed gearing with the axles of the wheels. When not in use the crane can be transported from place to place by means of wheels, which can be raised or lowered by the action of a screw, and when not in use they may be drawn up out of the way of the circular rail.

Fig. 1 of the engravings is a side elevation, and fig. 2 a plan of the machine. On a strong and suitable frame A, composed of heavy pieces of timber, is mounted an arm or jib D, which is made as long and at as great an inclination with the frame as possible. The frame A is carried and supported by a carriage B, which moves along a rail by means of the wheels, and also by means of the wheel *i*, which moves on the circular rail E. On the frame A is also mounted a boiler F, and a steam engine G, which, through the crank C, gives motion to a pinion, which turns the large wheel K fixed on an axle carrying

PONCINS' STEAM CULTIVATOR.



the drum or roller I, on which is wound the lifting chain; the chain passes round a series of pulleys in the usual manner, and is connected with a trough or receiver L, by means of the links *i*, *i*, and a hook. The arm or jib D is composed of two pieces of wood, forming an acute angle whose lower extremities are united by means of the cross bar which rests on the frame A, and the pieces are also strengthened by cross pieces. The whole machine is centered on a bolt or pivot N, a cross piece passes under the rails of the carriage B, by means of which a greater counterpoise to the weight to be lifted is obtained. A donkey engine R on the frame A gives motion to a pinion, which is connected by means of gearing with a wheel bearing on the surface of the rail, which turns the whole machine round the centre N. Two other wheels, one on each side, serve to steady the machine. The action is as follows:—Supposing that the machine is employed to lift a shell or trough filled wih sand, coal, or other substance from the interior of a barge or lighter, and after having raised the desired quantity to a certain height it is wished to unload the same into or at any particular place; to effect this a rod, having a cross piece M attached, presses against the top of the shell or trough whilst it is being wound up, obliges it to tilt, as shown, and thus empty its contents into a railway truck, or other vehicle. The steadying wheels, before referred to, are capable of being raised or depressed by means of a screw, acted upon by suitable gearing, so that in transport they can be drawn up out of the way.

PONCINS' STEAM CULTIVATOR.

This invention has been recently patented by Mr. E. Poncins, of Feurs, France.

The apparatus consists of two frames or wheel trains A, B, which work alternately, one for the up travel and the other for the down travel. Each frame carries three tools or implements placed diagonally on different lines, so as to produce three furrows close to each other. The engraving shows three ploughshares *a*, *a*, *a*, on the frame in position for working, and three like shares *b*, *b*, *b*, raised out of the earth. The cultivator is drawn by means of a rope, and is directed so as to produce the furrows desired by the operator on the seat *c*, by means of the rod *d*, which acts on the axles of the front wheels; by this contrivance the driver or operator is enabled to incline the said axles in relation to the axis of the cultivator, and thus drive it in any required direction.

The frame B, which is before the operator, remains inactive during each travel, the shares *b*, *b*, *b*, dragging on the ground being hinged or jointed at *g*. By withdrawing the hinge pins or bolts *g*, any other cultivating tools may be inserted. A line of three furrows having been cut at one travel, the operator turns round on his seat, and the return travel is operated without moving the steam engine, the wire rope and a windlass being arranged to that effect. The tools *a*, *a*, *a*, by pressing on the ground swivel on their hinges and become inactive, whereas those *b*, *b*, *b*, get into action for tilling. The height of the frame above the ground is regulated by means of the set screws *h*, *h*; *m* are blades acting as guards or fingers for clearing away stones.

FANSHAWE'S IMPROVED MODE OF CATCHING FISH.

Mr. H. R. Fanshawe, of Leadenhall-street, proposes to allure and thereby facilitate the capture of fish in the following manner:—

He makes use of a submerged or subaqueous light, the light being derived from electricity, or from the ignition of phosphorized oil or gas; or a sufficient volume of light may be obtained by reflecting light from above upon submerged reflectors.

A globe of glass, either plain or coloured, containing a lamp, is supplied with air by the use of flexible tubing, the said globe being protected by means of a strong wire net or a suitable metallic frame.

The decoy light or reflector is placed or disposed in such a manner at the required depth that the fish are attracted thereto by the light. The illuminating apparatus may be lowered to the required depth, by any mechanical arrangement which will answer the purpose desired, from a boat, having a well at or near the centre, for the purpose of more conveniently superintending the working or adjustment of the decoy arrangement, and of seeing when a sufficient number of fish are collected, so that the boat may be removed for the purpose of closing the net or nets. When the electric light is employed, the lantern may be sunk before ignition, and the light extinguished before its withdrawal.

Where lines are used, as for cod, salmon, and other fishing, it is proposed to employ as a decoy, at or near to the bait on the usual line, a small globe or other shaped vessel of glass, which is illuminated by the introduction therein of luminous fluid, such as common phosphorized oil, or by other means. The upper end of the flexible air tube is supported above the surface of the water by a float. The globe or vessel is protected by surrounding it with a frame or network of wire.

A DIFFERENTIAL WAVE IN A STRATIFIED FLUID.*

This was a curious phenomenon, on which the author had stumbled rather than one at which he had arrived by regular investigation; indeed, the regular investigation seemed to present difficulties greater even than those which attach to simple wave motion. A trough, having plate glass sides and a close cover, was partly filled with water, and partly with spirits of turpentine floating on the water, tinted pink to mark the surface of separation. When the liquids were at rest, this surface was of course level; but by a properly managed effect of disturbance, a regularly formed wave could be propagated in either fluid, traversing the surface of separation, and leaving the top surface almost undisturbed; indeed, it was not necessary that the latter should experience any disturbance whatever, since it was seen that the wave of stratification was then most regularly formed, when the superjacent fluid filled the trough completely, and was in contact throughout with the close-fitting cover. The velocity of propagation was greatly reduced as compared with what it would have been had either fluid stood alone, and this reduction of velocity should probably follow the ratio compounded of the square root of the increase in the work to be done, and of the square root of the reduction in the actuating force. Taking the subjacent fluid as the basis of the ratio, the former component would approximately be expressed by an increment, directly as the specific gravity of the superjacent fluid, and inversely as the thickness of the stratum (since the shallower the channel the less the velocity of wave propagation). The latter component would be obtained by comparing the difference of the specific gravities of the two fluids, with the specific gravity of the heavier. A wave of this character, being a travelling mass or volume of unchanging form, displacing a fluid by pure wave-law as it travels, should be the most correct type of the curve of least resistance. Some of the phenomena developed are suggestive of possible meteorological conditions, since they show how by a wave-motion once established in atmospheric strata of unequal densities, there may be transmitted a state of disturbance under which contiguous volumes of air are mutually urged in precisely opposite directions; the velocity of translation being greatest at the surfaces of stratification. This was curiously illustrated by Mr. Froude's experiment. The continued agitation undergone by the fluids in the creation of waves had developed the singular feature of a froth of the lighter fluid hanging downwards into the heavier, and when the trough was slowly tilted and set down again, so as to develop part of a very long wave of stratification, the opposite translations of the contiguous surfaces rolled up the intervening froth into volumes, closely representing the familiar aspect of a mackerel sky.

THE LONDON ASSOCIATION OF FOREMEN ENGINEERS.

A numerously-attended meeting of members of this society took place in their Rooms, in St. Swithin's-lane, City, on the night of Saturday, the 2nd inst. The chair was filled by Mr. Newton, of the Mint, President, who read a Paper on

Marine Propulsion.

The subject, Mr. Newton said, was one of acknowledged importance, and he trusted that his remarks in reference to it might be taken for what they might be worth, and the plan he advocated criticized freely. It had been assumed by many that the screw system of propulsion must be considered as final; and that only in the direction of improvement in the form of the screw itself, or in the application of twin screws, did there exist hope for obtaining increased and economical speed in steam vessels. He did not altogether share in that assumption, and he trusted that shipowners and marine engineers would give a patient hearing to the statements he intended to make that evening.

Mr. Newton said that his friend Mr. Vaile had proposed to apply to vessels one or more endless-chain propellers, with floats adapted in form, dimensions, and number, to each particular vessel to which they might be attached. Some might urge that there was no novelty in the endless-chain propeller, and that it had been tried and "found wanting." The improvements in the details, and indeed in some of the main characteristics of Mr. Vaile's form of propeller, were such as to distinguish it from all previous efforts of a similar kind. Those improvements consisted in the form of the floats their mode of attachment to the chains, their perfect feathering properties, and the total submergence of the entire apparatus.

---

* Abstract of a Paper read before the last General Meeting of the Institute of Naval Architects, by Mr. Froude.

The breadth of the floats might in all cases be made equal to the diameter of the chain-wheels minus the diameter of the shaft and a few inches of clearance. Thus, for example, if wheels of 10 ft. in diameter were used, with shafts of 12 in. diameter, and 6 in. were allowed as clearance, the floats would be 8 ft. 6 in. in breadth, and as long as the beam of the ship would permit.

Now, as every portion of the surface of these floats would be put into the water without exercising any appreciable leverage against the engines, would travel with equal velocity, and have a direct thrust aft, it seemed clear that a far more effective hold of the water must be obtainable than would be the case with screw or paddle-wheel. Up to the present time, it had been found impossible in practice to move vessels at high rates of speed without increasing the penalties of an enormous expenditure of steam power and a ruinously large consumption of fuel. This was owing mainly to the limited area of the propelling surface brought to bear upon the water in proportion to the bulk and weight to be moved through it. Whether screw or paddle-wheel were employed, the results were the same.

In the paddle-wheel the acting surface of the floats was small as compared with the diameter of the wheel itself, and this again was limited by obvious circumstances. Each additional foot of diameter constituted so much additional leverage against the engines, without yielding any adequate advantage. In the case of the screw, this extent of propelling surface was limited by the distance between the keel of the ship and her water line.

The feathering floated endless-chain propeller of Mr. Vaile, on the contrary, admitted of the employment of a number of floats acting simultaneously on the water, and of those floats being of far greater length and breadth than those of the ordinary paddle-wheel.

This was one of the principal features of the plan which Mr. Vaile had invented, and which Mr. Newton now advocated. There were, however, said the reader of the Paper, many others, and among them the complete submergence of the propeller, and its simple yet beautiful mode of producing the feathering movement.

The Paper, which was well illustrated by drawings and diagrams, was followed by a discussion, in which Messrs. Keyte, Onbridge, Briggs, Walker, Miller, M. Jones, and others shared. An adjournment of the further consideration of the subject to the next monthly meeting was finally carried. Mr. Vaile, who was present, successfully combated some objections raised.

Meetings for the Week.

Mon.—*Royal Geographical Society.*—I. "Arrival of the Expedition under Captains Speke and Grant at Khartûm, on the Nile, from Zanzibar." II. "Despatches from Governors Sir H. Barkly and Sir G. Bowen—Landsborough's Traverse of Australia." III. "On Madagascar," by Lieutenant Oliver, R.A., at 8.30 p.m.

Tues.—*Royal Inst.*—"On Sound," by Prof. Tyndall, at 3 p.m.

Inst. Civil Engineers.—I. Discussion upon Mr. Zerah Colburn's Paper "On American Iron Bridges." II. "On the Communication between London and Dublin," by W. Watson, Esq., at 8 p.m.

Wed.—*Soc. of Arts.*—"On the Collection and Utilization of Excrementitious Matter," by J. L. W. Thudichum. II. "On a System of Earth Sewage," by Rev. H. Moule, at 8 p.m.

Thurs.—*Civil and Mechanical Engineers.*—"On Giffard's Injector," by W. Maw, Esq., at 7.30 p.m.

Sat.—*Royal Inst.*—"On Language," by Professor Max Müller, at 3 p.m.

The French Academy of Sciences has named Admiral Fitzroy corresponding member for the section of geography and navigation, in the room of the late Sir James Clark Ross.

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the Mechanics' Magazine at the rate of 6d. per line, or 5½d per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisments.

All communications should be addressed to the Editor, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

Received.—W. B. M.—T. J. M.—J. C.—J. K.—J. H.—T. J.—R. S. T.

W. M. (Manchester).—All the advantages of the cellular structure you propose for armour-plating have been obtained in a much cheaper way than by "drilling 12-inch round holes to the depth of 10 in. in plates 12 in. thick, and then plugging these holes up with wood." As you are a mechanic, did you ever calculate the expense of, for instance, drilling out a locomotive tube-plate?

J. C.—The places in London where you can see the printed specifications are—the Free Library, 25, Southampton-buildings; the Patent Museum, South Kensington; the Library of the British Museum; and the Library of the Society of Arts, John-street, Adelphi.

S. W.—Bourne's Catechism of the Steam Engine (Longmans) will probably suit your purpose best. The price is about 6s. or 7s. we believe. The more complete treatise on the steam engine, by the same author, costs about 30s. As you say you wish for information that will be of use to you in a factory, then, perhaps, the work of Mr. Hopkinson on the Indicator, Weale, High Holborn, price 12s. 6d., might suit at a later period of your studies.

J. W. A. S. (Deptford).—Perhaps the main reason that higher pressures of steam are not used in marine engines is the general popular prejudice against high-pressures. The article in our last number, on Compound Engines, will partly answer your question. You cannot practically condense very high pressures of steam with much resulting economy. This must be evident to you on reflection. A cubic inch of water raised into steam of 15 lb. pressure will require about 22¼ cubic inches of water at 50 deg. to get condensed. The very utmost theoretical gain of pressure from a vacuum is 15 lb. There are only 33 deg. less heat in a given weight of water, raised into steam of the pressure of the atmosphere, than if the water were raised into steam of 90 lb. pressure.

Correspondence.

◆

AN ATLANTIC TELEGRAPH.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—I observe the communication of "An Old Sailor," and the further communication of Captain Selwyn, and beg to make the following remarks thereon:—I have first to remark, by way of caution, that new ideas have often been pronounced to be impracticable, though ultimately found to be quite the opposite, and to be highly useful; and it is proverbial, in the history of improvement, that men, apparently the most competent to judge, have often been found to be the most wide from the mark in their first opinions on such matters. It would of course be most arrogant in me to say that "An Old Sailor" and Captain Selwyn are not right, but they may both be wrong, and the probability on this point can only be determined, not from their concurrence in opinion—for concurrence in error is quite a common thing—but from the facts or alleged facts adduced by them in support of their opinion, and their reasonings thereon; which we shall therefore, now proceed to examine.

"An Old Sailor" alleges that there are insuperable difficulties attending the placing of the buoys in such deep water. There may be, but he has not stated what they are. I answered—successfully as I think—Captain Selwyn's specific objection on this point, who, it appeared to me, very strangely assumed that only *one* ship would be employed in mooring the buoys and laying the cable—a most unnecessary limitation. Nor, I suppose, did he keep in view the vast facilities afforded by nature herself in doing so, if we will only condescend so far as to have the plain good sense to adopt the northern route.

"An Old Sailor" further alleges that there are insuperable difficulties in ascertaining the depth to within the number of fathoms I propose to submerge the buoys. On this point I may remark, that I specified a depth of from 20 to 30 fathoms, for the sake of giving an idea of my meaning, and as what would be the desirable depth to aim at; but its perfectly exact attainment in practice could not, it is believed, be accomplished, nor would it be at all essential. The objects in view are—to avoid *surface* motion of every kind, on the one hand; and *great* pressure on the cable, on the other. The former object would be arrived at, according to all the authorities, by mooring the buoys below from 30 to 50 feet under the surface; and on the other hand, the pressure on the cable would be of little moment down to 100 or 200 fathoms, or even more, so that "An Old Sailor" can have all that range if necessary; by means of which, it is supposed, the insuperable difficulties seen by him on this point will disappear, while the objects aimed at will still be attained. But my view, that from 20 to 30 fathoms would be the most desirable depth to moor the buoys, is in perfect consistency with the preceding statement.

I may remark, generally, that alleged "insuperable" difficulties have been so often overcome by skilful selection and adaptation, that it behoves us to be extremely careful when and how we use the word. To state objections is most commendable; in the present case I feel under great obligations to "An Old Sailor" and Captain Selwyn for doing so; but to declare difficulties to be insuperable requires not merely experience or practical knowledge on the particular point (which sometimes, however, it is well known, has a prejudicial effect), it also requires the knowledge of what might be, as well as what is. It often requires us to view the matter from a different point than that from which we have been accustomed to view it, and it also requires the possession of a calm, deliberate, unbiassed judgment.

Having thus examined the facts and reasonings of "An Old Sailor" in support of his opinion that my scheme is impracticable, he and others will judge whether I have not shown, for the various reasons above assigned, that they are groundless and untenable, or, at least, inconclusive. I hope he will favour me with a reply; but, in replying, he will keep in view that the number of the buoys, their size and distance, their depth in the water, and the best means of mooring them are all matters of adjustment. He will also be so good as keep in view that there is such a thing as the northern route with its short-sea distances.

To return to "An Old Sailor's" communication. He says that "weed, barnacles, &c.," would accumulate on the cable, which would thus drag down the buoys so far that the enormous pressure would cause them to collapse."

A telegraph cable, as proposed, is a very different thing in nature, position in the water, use, and, it may be added, in every other respect from a ship's bottom—the adhesion of weed and barnacles to which is what I suppose "An Old Sailor" reasons from. How the matter would stand as to the supposed adhesion of weed and barnacles to the cable would, if necessary, be so far a matter of easy experimental inquiry. But supposing they did adhere, would weed and barnacles be, on an average, heavier than sea water? It is extremely questionable that they would be heavier, to say the least; and, in the meantime, I do not believe that they are. Consequently, if this be so, they would not impair the floating power of the cable, but would, perhaps, rather assist it. But it is also known that weed and barnacles have their limits as to the region where they grow, and, it is believed, that the depth at which the cable would lie, would place it entirely beyond their reach. On these grounds I apprehend no difficulty from weed and barnacles. "An Old Sailor" adds "&c." to the weeds and barnacles, but what that means I do not know, and I question much if he knows himself. I trust that, in making this remark, he will not think me deficient in due respect, as in scientific matters we ought always to be as perfectly clear as possible.

I may here remark, that, when land telegraphy was first commenced, the wires were often laid in the earth—this being then reckoned the best and safest method. This method is analogous to ocean bottom telegraphy. Now, however, land wires are, without exception as far as I know, suspended on poles and carried through the atmosphere—this method being analogous to ocean surface telegraphy. The analogy is both interesting and instructive.

"An Old Sailor" further proceeds in his communication to say that the arguments advanced why a clabe should not lie on the ground, are, he thinks, based on difficulties more imaginary than real. Yet, of the *three* objections—all fundamentally important—stated by me against such a course, he fully and unqualifiedly admits the *first*—namely, the thorough inaccessibility of the cable laid at such a depth for repair.

As to the *second*—the pressure of the great superincumbent mass of water on the cable at such a depth—he reasons, it seems to me, very erroneously, in consequence of not rightly apprehending the facts. He likens the pressure of the water on the cable to the pressure of the air on our bodies; and, as the latter does no ill, infers that the former would do no ill either, but rather good. But it is submitted, that, if it could possibly happen that the air could be entirely excluded from our porous bodies without involving a fatal termination, nevertheless the air, by its constant great weight and great elasticity, would be unceasingly endeavouring to get into our bodies, and would, no doubt, ultimately succeed. So, in the same manner, has the water of the ocean been found to act. Need I remind "An Old Sailor" of the well-known experiment of sinking an empty bottle, tightly corked, a comparatively short way down into the ocean, and, when forthwith brought up, it is found to be full of water, though still tightly corked, thus clearly showing the intense pressure of the water as the depth increases, and its access, through the pores of the glass, into the inside of the bottle. I have also seen it stated, that, when a piece of wood is sunk a good way down into the ocean, it always comes up thoroughly permeated with water, and deprived of all floating power. These most decisive experiments ought fully to satisfy "An Old Sailor," that the *second* objection is as well founded, as he has admitted the *first* to be; and being, from its very nature, a thoroughly fatal objection to bottom ocean telegraphy, I do not see how he, or any one else, should any longer advocate such a worthless system. As for submitting a part of the cable to a pressure of 500 atmospheres, as he proposes, he must recollect that such a pressure, as always applied, lasts for a comparatively short time only; whereas the pressure of the water at the bottom of the ocean never ceases; and, from the excessively insinuating nature of water, must, it is believed, at such a great depth, always ultimately prevail in gradually forcing the water through the pores of the insulating material into the wire, while the electric action of the cable will in like manner gradually cease. This, I have no doubt whatever, is the true cause why deep-sea cables have hitherto always failed, and will fail, so long as they continue to be be laid on the ground. And, if surface telegraphy cannot be realized, we may in that case, give up all idea of ever having permanent telegraphic communication with America across the ocean. Of course, long stretches of continuous cable, such as from Ireland to Newfoundland, aggravates the evils of ocean bottom telegraphy, and brings them all the more speedily to a climax. Hence the reason why the Atlantic Cable, laid between these places, worked for so short a time.

Besides, what has been above stated on this point, it is an ascertained fact, as referred to in a former communication, that pressure diminishes the conducting power of the cable—this, therefore, being an additional reason for preferring surface telegraphy.

As regards the *third* objection to laying the cable on the ground—namely, the utmost uncertainty as to the suitability of the bottom for the cable, "An Old Sailor" seems to think that it is entitled to no weight whatever. This is going too far, though it is believed that there is a great deal of truth in what he says on this point. But, removed so greatly as the bottom is from all observation, we cannot say how prejudicially it may affect the cable at particular places; and there can be, no doubt, that water, as a rule, is much softer than the bottom. On these grounds alone it is highly desirable to keep the cable as much as possible in the water, without touching the bottom, but other grounds might, if necesssary, also be advanced.

I must conclude for the present, as I do not wish to take up more of your space in one number. The preceding remarks, it may be seen, apply more especially to the communication of "An Old Sailor," but I shall beg leave to trouble you with another communication with reference to that of Captain Selwyn's.

H. K.

Edinburgh, 4th May, 1863.

IRON AND WOOD.

Sir,—One of your correspondents (on the 3rd of April) advocating iron, stigmatizes wood backing as good for nothing. He (the iron partisan) is "more convinced than ever that wood backing is a blunder —that it is, in fact, the main cause of the destruction of armour plates under the fire of artillery." Poor wood! This verdict settles his case as a backer, and actually makes him out a culprit. But let him challenge iron to change places with wood, while he (wood) boldly takes his tour of duty in front. Suppose, for instance, the penetrative force of the projectile, and the resisting power of the iron plate, be so nicely balanced, that the former will just carry the projectile through the armour, and expire in the effort. Then let honest wood, in the shape of 18 in. of timber (or a good deal less) meet the shot on its way to the iron, and it is plain that enough of the penetrative force, under the circumstances supposed, would be absorbed to render the projectile harmless to the armour.

But shells (says iron) would set wood on fire. That is not so certain with iron backing, for there would be want of air current. At any rate (rejoins iron) the shell exploding would scatter the wood in fragments. So it might, but the splinters would fly into the sea, and not into the ship through the iron armour.

There would be no harm, nor any great waste of either money or ingenuity, in trying a single experiment or two among the number at Shoeburyness, just to see wood's behaviour with iron armour *behind* him.

Perhaps an iron-plated ship in a wooden hull might prove the best sort of man-of-war to contend with enemies both above and under water—the hostile broadside and the sunken rock. And of the "Birkenhead" and "Royal Charter," there might not be now such piteous tales to tell if they had been sheathed with timber. *Larch* is said to be slow in taking fire; and if that is true, as it is lighter and more buoyant than oak, would it not be preferable for the outer hull of an iron ship?

One of the "Lignums."

May 1st, 1863.

THE VALUE OF WOOD BACKING TO ARMOUR PLATES.

Sir,—In your account of the proceedings at the Institution of Naval Architects, it is reported that Mr. Scott Ruesell, in the Paper he read at the meeting, stated that the timber backing to the armour of the "Warrior" did no good, and that the weight of this wood would be better exchanged for iron plating. It is surprising that a gentleman of the practical knowledge which he must necessarily possess, should utter the former of these opinions. It would really seem that he entertains the extraordinary notion, as false in theory as it is contrary to all experience, which your correspondent "Civilian" advocates—that elasticity is an evil and rigidity is a benefit, when the object is to prevent a shot penetrating the armour—unless, indeed, he limits his idea of the inutility of wood backing to the incidental evil of favouring (not wholly producing, it should be remembered) the fracture of the bolts that fasten the plates. But this evil being merely of a practical nature, is susceptible of practical remedies. The second opinion, however, if it implies no more than, that weight for weight, the resistance opposed by wood is less than the resistance opposed by iron to the penetration of shot, and that, in reference to this particular alone, wood might be better exchanged for iron, involves only an unsettled point of inquiry deserving experimental investigation. In my discussion with "Civilian," I always treated it as an open question, but I will now, for the sake of argument, admit that wood is inferior to iron in this respect, and yet the question will still arise—can wood backing be dispensed with? I think not; and I give this opinion, not now because of the greater difficulty which an elastic resistance, as contrasted with a rigid resistance, presents to the piercing of the armour plates, for I am assuming that they will be so improved in quality and increased in thickness that even a 300-pounder will not be able to force a passage through them, but because I have in view the disastrous effects of such heavy projectiles in the way of concussion, by breaking up the iron framing of the ship, if the blow be not softened, and also if it be not distributed over as large a surface as possible.

It is the intensity rather than the magnitude of the shock—the latter being, in truth, unalterable—that snaps the fastening bolts and the iron girders, and it is folly to contend against it, under the conditions of buoyancy which the case imposes upon us, by sheer strength of resistance. We must manœuvre with the foe and oblige him to change his front. Although our engineers, being most conversant with the property of rigidity in iron, may be supposed to regard it with the affection of the currier for his leather, and although habits contracted in the pursuit of abstract science might have a lingering influence upon the judgment of the more scientific among them, yet surely the latter might have brought to their recollection how the more practically minded of their confreres interpose buffers between railway carriages and fenders between ships. In fact, we must adopt yielding tactics with such an enemy as impact, and not brave it out with rigid solid resistance; we must give sensible duration to what otherwise would be the almost instantaneous act of impact, by prolonging opposition to it in distance in the direct line of the action; and we must also involve it in operation over a greater area of resistance than that of the initial collision, that is to say, we must distribute the action of impact over greater time and greater space, not only to obstruct the piercing of the armour plates (which, however, is not the point I am now discussing), but for the purpose of preventing the blow from being transmitted with the same intensity with which the outward surface is struck. This distribution and diffusion of the hostile force is the natural course to take to defeat that concentration of it in time and space which the artillerist adopts against us—the first, by giving the greatest velocity to the shot; and the second, by throwing the greatest weight into it under the same area of impact, by making it take the form of a bolt instead of a sphere.

The effect of this concentration, in respect to the piercing of the armour plates can be defeated, at least it is possible; but the concussion of the impact is inevitable; and it is the destructive tendency of this upon the ribs and skeleton of the ship, or upon the turrets of the "Monitors," on which our American cousins rely, and which prompts them to cast such enormous guns. Neither can the magnitude of the concussion be lessened by any contrivance which does not cause the shot to glance; for it must wholly correspond in this case to the *vis viva* of the projectile, there being no deduction here in regard to relative velocity. But, on the other hand, the character of the concussion can be altered, and its destructive tendency mitigated, by a change in its form—that is to say, the intensity of pressure, potential at the moment of impact, and actual if meeting with adequate resistance, can be moderated, in the course of its transmission through the side of the vessel, by an alteration in the relative value of the terms of the action, considered as the performance of work. This, first assuming that we are speaking of uniform, or, if otherwise, of mean resistances, an actual pressure for a distance of 3 in. against the resistance of iron armour (being, say, 2 in. in the indentation, and 1 in. in the deflection of the plate), will find its equivalent in one-half the pressure for a distance of 6 in. against the integral resistance of a wood-backing (say, of 20 in. thick), in opposition to deflection to the extent of the said 6 in. Thus, the terms differ, whilst the amount of work done, being the product of the terms, remains the same. Now, this taking of the lineal measure (tantamount to the diffusion of action over time), is on the assumption that the area of resistance will continue the same, which of course, is not the fact; nor, is it so, even in the case of the passage of shot through wood. But, it is also assuming what is doubtful, touching timber backing, that the necessary degree of rigidity proper for the frame of a vessel, will admit of a deflection of 6 in.; but this want of exactness in the illustration will not affect the argument. The pressure, it will be seen, does not terminate with the initial action, but is propagated, not only through the side of the ship, but throughout the entire vessel, and thence, indeed, to the water, and so on to whatever extent pressure is communicable. This proposition is, however, subject to the qualification that the action may, to a certain extent, be spent by transformation into molecular phenomena, as indeed is sensibly manifested in this very case, when heat, light, and perhaps electricity, are evolved in a flash on the shot striking the plates.

The pressure being diffused by propagation, its intensity will not only be diminished for a given area upon any material subjected to it, in proportion to the greater distance over which integral resistance is oppossd to it, but also in proportion to the greater area over which it ultimately acts. Now, the ultimate area—ultimate I mean so far as we are practically concerned—is enlarged proportionally to the square of the distance from the apex of the truncated cone, formed between this area and the initial area of the impact, the distance between the two being the thickness of the side of the vessel. But the extent of the enlargement will depend also upon the angle at which the pressure diverges, and that again upon the nature of the materials through which it is transmitted, and also, as I apprehend, upon some ratio, inversely however, of the velocity with which the blow is struck. Thus the work done in the concussion will be diffused in superficial as well as in lineal space. For example—let the initial area of the impact be one square foot (rather exceeding that of a 13-inch shot), and the pressure on the skin be distributed, in virtue of the angle of divergence and of the thickness of the backing, over a surface of 4 square feet, then, if the deflection being equal to the range of the pressure in and of the armour plate, namely 3 in., the stress on each square foot will be one-fourth of the intense initial force of the impact, and one-eighth of the same, if the deflection be extended to 6 in., in accordance with the suggested lineal modification of the work. And as to a rib supporting this area, the stress on each foot of its length will be respectively for these deflections, one-half and one-quarter of the pressure of impact. If the frame of the vessel were made as rigid as "Civilian," Mr. Scott Russell, and others appear desirous of rendering it, so that it permitted only a slight deflection (say of 1 in.), then the foot lineal of the rib opposite to the square foot of the collision, would have to sustain three times the intense initial pressure of the impact, if the wood backing were removed, and one-and-a-half time if allowed to remain. Each square foot on the skin would have to sustain three-quarters of the same pressure.

We thus see the immense effect, whether this calculation be exact or not, which the presence of rigidity and the absence of backing have a tendency to produce in the fracture of bolts and iron ribs. I am aware that something may be said in the way of modifying this view of the subject, in favour of conclusions leading to a medium beneficial result, as between intensity of pressure on the one hand, and extension of the strain on the other; but then it would be necessary to disprove that it is the *jar*, or the suddenness of the strain which causes the iron to snap. Besides, it would be allowed by such objectors that suddenness doubles the strain. I believe it does more than that, if anything at all, but I cannot now enter upon the subject.

It is possible, and, if I mistake not, it is found to be the fact, that in the passage of pressure the integrity of the wood in the backing is destroyed in the immediate vicinity of the blow. This destruction would be gladly accepted vicariously for that of the iron girders, but, unfortunately, it has not that effect, for certainly it tends to diminish, without wholly checking, that divergency of the pressure which distributes it over a larger area; for divergency in some degree would take place even in a backing of sand. It is also so unfavourable to, as it would be wholly destructive of, the integral resistance of the backing, if it extended to the length and area of the pressure through the wood. These considerations, however, seem to account for the appearance of a small area at the back of the targets, showing signs of a greater comparative intensity of pressure relatively to the larger area surrounding it, and also a more circumscribed pressure upon the whole than we should have expected to find.

Allow me to make one more incidental remark. The mathematical ideas embodied in this exposition of the subject are these:—that *vis viva* is transformed into work; that work is transmitted from body to body, such bodies being rigid systems of particles; that in such transmission there is no sensible loss, whatever may be the fact in the transformation; and that the terms can be changed with perfect equivalency from a greater pressure over a lesser distance, to a proportionally lesser pressure over a greater distance. Now, these ideas, and all needful practical deductions therefrom, can be expressed without necessarily using symbols, and adopting an algebraical treatment thereof, and be brought home, in ordinary language, to practical and even popular apprehension.

Yours truly,
BENJAMIN CHEVERTON.

P.S.—Since this letter was written, Mr. James Chalmers' target has been tested, affording a singularly appropriate illustration of the preceding observations. An explanation of the efficiency of this target may be drawn from a consideration of the penultimate paragraph of this communication. The alternate layers of iron and wood, firmly bound together, besides being connected by a base plate, and presenting their edges to the pressure, tend to preserve the integrity and elasticity of the wood, and to maintain intact a rigid system of particles, so as to yield an integral resistance of the entire body thus treated, to the exclusion of destruction in detail, and the transmission of pressure from particle to particle. A more elastic resistance is thus established. Doubtless, also, the ultimate area of the pressure is incidentally enlarged. But this is not the point to which I attach importance; for, as I have already said, there will exist an angle of divergence even through a backing of sand. I really cannot help making the remark, that I not very long since recommended in your pages this very arrangement of wood and iron for the construction of the frame of vessels, and that upon it, as a foundation, I proposed to place the armour-plates.—B. C.

NAVAL CONSTRUCTION AND DOUBLE PROPELLER SHIPS.

SIR,—Observing in the last number of the MECHANICS' MAGAZINE an article on "Twin Screw Steam Ships," in which reference is made to the interesting Paper lately read before the Society of Arts, by Commander Symonds, on the subject, I trust you will do me the favour to allow space in your valuable columns for the following:—

It may be generally supposed that the mode of applying two screws, as Commander Symonds and Mr. Roberts advocate, is the only practicable way of applying them, but such is not the case. It has, however, one advantage, that is, that no other method has yet been tried, and, so far as the late experiments have gone, this system of propulsion has proved to some extent a success. These experiments, however, have only been made upon very small vessels. The inquiry that will follow, as a matter of course, will be how the system is likely to answer for ships of the large class, intended for high speed, and consequently having long tapered after-bodies. In such a case, the propeller shaft projecting from the run at the end of bilge must necessarily be of great length, and, whilst more exposed, will require several stays or supports, which we shall be obliged to secure to the body of the ship, offering as they would immense obstruction to the free flow of the fluid from the after-body of the ship in motion. At a slow speed this is not important, but at a great speed these supports or frames will greatly impede the ship's progress. Worse than that, they are liable to be carried away, and then what becomes of the screw shaft? The plan Commander Symonds advocates may suit small vessels with a full and short run, but it will never do for large ships intended for speed.

About the beginning of March, 1862, my attention was drawn to the reports of the trials then being made with the new iron-clads, and the unpleasant discovery that considerable difficulty was expended in making them steer. The question again and again recurred, how was it that these ships, having such beautiful and noble forms, and fitted with every available appliance for facilitating their steerage, would not answer their helms as promptly as other ships? No reply to that query seemed so satisfactory as the one that the cause was owing to the weight of solid metal upon their sides. In the endeavour to find a remedy, or a means to make them perform their revolutions rapidly, I thought of applying two screws—namely, "one under each quarter," and then the idea of double or bi-formed after-ends was evolved, which brought with it a train of other ideas that are likely ultimately to bring into existence a totally new form of ship, adapted both for the Navy and the mercantile service. A model of mine is now on view at the South Kensington Patent Museum, put there last October, which was made with the object of showing the double after-ends of the two keels, extended and meeting at the centre of bow, about the light line of flotation, supplying a new idea for a bow which is hollow or concave before it meets the flat bottom, and thrown back above the water-line, to prevent the seas passing over the rail on to the deck—a sea would divide itself and fall at each side before it could reach the rail. The form of the ship beneath and above the plane of flotation has been since somewhat modified, as it has been found necessary since to mature and perfect the form to attain certain objects to which space forbids me now adverting.

The present style of model belongs eminently to ships to be propelled by sails, and partly suited for paddle-steamers, but not at all for screw ships. In the first, we want the greatest lateral resistance attainable, and so must have the long and deep forefoot and great depth of deadwood aft, and the ship must sit deep in the water to enable her to "hold her own" when the wind blows across the beam, which is nearly always the case. These conditions are not required for the ship to be propelled like the fish, whose propeller is precisely in the same place and in such a position that it drives all the impeding forces before it. Therefore the curves of the longitudinal sections of the after body must correspond in their form and fine taper to those belonging to the fast fish, if the force of suction may be done away with, which we find to be so formidable an impeding force where it exists, as it does in badly formed ships and those having a short and full run, or after line, especially near the loaded section. In sailing ships this fulness cannot be dispensed with, if we have only one after-end, from the danger of pooping in running before gale. In the present style of ship, the force of suction commences just below the surface of the water, and diminishes in strength and area in the direction of a diagonal section towards the bilge. In the case of finely-tapered lines aft, its area is much reduced, and can only exist within a very narrow compass immediately below the surface, whilst the ship is sailing at a moderate speed; but increase the speed, and its area spreads, following the line mentioned, its strength becoming greater in proportion to its increased area. Secondly, the area of friction is confined to the bow and that portion of the ship's side bounded by a direct line, or it may be a curve, according to the form of the body, which we may produce in our imagination, from a point a little abaft the forefoot to the knuckle of the quarter, its intensity being greatest on that portion of the bow between the stem and the cheek. A long fine bow upon a clipper ship may look very pretty, and be an advantage to her in gaining lateral resistance and so afford the weatherly qualities, so desirable in a sailing ship; but it will not be favourable to speed, since the area of friction has thus been so much extended; and it becomes a question of some doubt whether even a long bow line, under these circumstances, tends to increase lateral resistance; for if the other impeding forces were reduced to their minimum, and so that the ship may pass through the fluid more quickly, she would make up for any deficiency of lateral resistance afforded by the long bow line and upright stem. The element of friction in long ships with great length of bow line, becomes of considerable importance.

In screw-propeller ships we do not require a long fine-tapered wedge bow, though the straight line is better than the concave line, since we have no occasion to think how we may best obtain weatherly qualities; in her case we want to apply the form of least resistance to her progress direct ahead. She is not intended to travel partly sideways, as the crab, but to go right forward, like the fish. Let us take a fast fish for our model. What is the form that the God of nature has given it? and what provision has He made for its movements through the silent deep—its habitation? The fast fish will supply us with beautiful curves, and a perfect form for a fast and safe ship, if we will but copy the model so placed before us. Suppose we take a porpoise or bointa, or any other fast sea fish, and cut it into sections, and suppose the transverse sections of this fish approximate nearest to the ellipse, then let us adopt the ellipse in procuring curves for the transverse sections of our ship. If, again, the longitudinal sections of the fish correspond nearest to the parabola, then let us apply these curves to the longitudinal sections of the ship's design we are engaged upon; and so we may now employ the science of Conic Sections in producing a ship's design with considerable advantage. Conic Sections could not be applied to shipbuilding before, simply because we did not want the curves for the design of a sailing ship, as the propelling forces are so often executed across the longitudinal axis of the ship. But now we are endeavouring to procure a design for a ship which must go before the propeller. We shall not have two forces, one acting against the other, as we find in the case of a ship with the wind abeam.

But the questions may be asked: How do you intend to make a ship sit upright if you adopt the fish as your model?—a body formed like the fish would cant upon its side unless weighted so as to maintain a central position, and this would not always be convenient. And again, if you adopt the long and finely-tapered line, such as we find in the fish, it would have so much buoyancy at the fore-end, and so little at the after-end, that the stern or tail would settle down in the water, and the fish's head would be found in that position which we should fancy it to assume if about to make an astronomical observation by gazing at the stars. The answers are as follows:—1st. We split the fish into two sections by a vertical plane its full length. 2nd. We separate them apart, say a distance equal to the semi-conjugate diameter of the ellipse, or the whole diameter, or three-fourths, as we should find most convenient, just according as we want the ship to float in shallow water and turn round quickly; the transverse diameter of the ellipse being vertical. We retain these conditions of the ellipse in applying this figure to the drawing.

We join the fish again by means of another set of curves, which, however, may be also got from Conic Sections; and so doing we have converted the fish into a monster of the deep; for it now has got two tails. The buoyancy of those two tails make up for the loss of buoyancy we should have experienced with but a single tail, and having removed a quantity of displacement under the breast of the fish, which will let the water meeting it slip freely under the belly, the two ends we have thus managed to balance. Our propeller shafts will be safe, as they are enclosed and protected, and offer no obstruction to the fluid passing along the run. We can gain a high speed and diminish the disagreeable and destructive motions, namely—rolling, pitching, plunging, and scending; these will be rendered so exceedingly smooth and easy that they will be scarcely felt. The ship will draw less water, at the same time affording greater displacement. The propellers we shall fit on to the shafts having great traction powers, with extraordinary propelling power, we can bring the ship up in her own length, and so back out of danger, when in action, if the necessity occurs, and turn her about quickly. The turret or shield system of defence she does not need, as her broadside guns can be trained as readily as the guns in a revolving turret. It becomes, therefore, a matter for the serious consideration of this country, when it is known that one good and perfectly constructed ship of war is of greater value (though she need not be of great dimensions) than a dozen badly constructed ships.

I am, &c.,
JOHN KENNEDY.

Shipbuilding Yard, Whitehaven,
6th May, 1863.

Miscellanea.

On Monday last, at the general monthly meeting of the Royal Institution—William Pole, Esq., M.A., F.R.S., Treasurer and Vice-President, in the chair—the secretary announced, that His Grace the President had nominated the following Vice-Presidents for the ensuing year:—Sir William G. Armstrong; William Pole, Esq., M.A., F.R.S., Treasurer; the Rev. John Barlow, M.A., F.R.S.; Sir Henry Holland, Bart., M.D., D.C.L., F.R.S.; Sir Roderick I. Murchison, K.C.B., D.C.L., F.R.S.; and the Lord Wensleydale. John Graham, M.D., and Cosmo Howard, Esq., were elected members of the Royal Institution. The following professors were re-elected:—William Thomas Brande, Esq., D.C.L., F.R.S., Hon. Professor of Chemistry; John Tyndall, Esq., F.R.S., Professor of Natural Philosophy. Edward Frankland, Esq., Ph.D., F.R.S., was elected Professor of Chemistry.

The following gentlemen were elected officers of the Manchester Literary and Philosophical Society for the ensuing year:—President—Edward William Binney, F.R.S., F.G.S. Vice-Presidents—James Presctt Joule, LL.D., F.R.S., F.C.S., &c., Robert Angus Smith, Ph.D., F.R.S., F.C.S., Joseph Chesborough Dyer, Edward Schunck, Ph.D., F.R.S., F.C.S. Secretaries—Henry Enfield Roscoe, B.A., Pe.D., F.C.S., Joseph Baxendell, F.R.A.S. Treasurer—Robert Worthington, F.R.A.S. Librarian—Charles Frederick Ekman. The Council—Rev. William Gaskell, M.A., Frederick Crace Calvert, Ph.D., F.R.S., &c., Peter Spence, F.C.S., George Mosley, Alfred Fryer, George Venables Vernon, F.R.A.S.

A new iron steamboat, built at Messrs. Rogerson's yard, St. Peter's, Newcastle, for the Tyne General Ferry Company, was launched on Monday. As a compliment to the renowned champion of the Thames and Tyne, this boat was to be called the "Robert Chambers." She had not yet been furnished with her engines and chimneys, but when she is fully equipped, as she will be, with machinery manufactured by Messrs. Hawks, Crawshay, and Co., she is very likely to prove one of the fastest boats of this rapid Red Star line. She is 99 ft. in length, 14 ft. beam, and 6 ft. 6 in. deep, and will be propelled by oscillating engines of 20-hoere power.

To the many and varied manufactures already existing and thriving in Birmingham another is about to be added—that of making files by machinery. A company has recently been formed to establish the new trade; its first works are to be erected in the neighbourhood; and as there is promise that the shares will be taken up, it is likely that operations will be commenced at no very distant period. Hitherto file-making has been one of the staple trades of Sheffield, but owing to the foolish, if not criminal, refusal of the Trades Unions of that town to permit the use of machinery in the manufacture, there has been a growing danger that the trade would be lost not only to Sheffield but to England. The Company intends to purchase the patents of Mr. Greewood, of Leeds, and of M. Bernot, of France.

SAFETY APPARATUS FOR GUARDING MINE SHAFTS.—Our attention (says the *Glasgow Morning Journal*) has been called, *apropos* to a letter which appeared in our columns on Monday last, from "A Miner" at Barkip Colliery, to an invention of Mr. William Reid, of Mount Vernon Colliery, by which the frequent fatalities to miners in ascending and descending shafts may be effectually prevented. As applied to an ordinary coal-pit mouth, the apparatus consists of an open rectangular timber frame, large enough to embrace the opening at the head of the shaft. This frame has its two ends hinged on so that it can be easily opened out for adjustment in its place, without interfering with the winding rope or cage. When the cage is down the shaft, this guard frame stands upon the pit mouth, so that nothing can fall down the shaft; but, when the cage is wound upwards, projections upon the cage come in contact with the feet of the frame, and lift it up clear of the pit's mouth. This action carries the guard frame clear away from the pit's mouth, so as to allow of full access to it, whilst, at same time, the cage itself forms the guard, and prevents anything from falling down the shaft. In this way a most effective guard is kept over the pit's mouth at all times of the actual working of the pit, whilst, at the same time, the protective apparatus does not in any way impede the operations of the miners or attendants.

TELEGRAPHIC COMMUNICATION WITH AUSTRALIA.—Two projects are in the field for connecting Australia with Java. It is proposed to lay the cable on the north-west of Australia, on the shores of the Gulf of Carpentaria, or to take it round to Brisbane, the capital of Queensland. At this point the cable would be in communication with the existing intercolonial lines; and New South Wales, Victoria, and South Australia would be thus brought into connection with the countries of the old world. The cost of laying the line from Java to Queensland is estimated at £1,100,000; but from Java to the north-west a cable could be laid for £243,000. Considering the many risks to which the submarine cables are exposed, and the uncertainty of their action, there can scarcely be a doubt as to the policy of selecting the cheaper route. The cost of such a land line has been estimated at £120 per mile, or for the whole distance from the north-west coast to Adelaide a sum of £177,000, which would make together a sum of £420,000 as the cost of the complete system from Java to Adelaide.

MR. LAIRD'S BILL FOR TESTING ANCHORS AND CABLES.—Mr. Laird has introduced a bill into Parliament for enforcing a standard proof to be applied to merchant ships' anchors and chain cables, and for the testing thereof prior to sale by the manufacturer or dealer. It is scarcely necessary to state that it is most desirable for the preservation of life and property that the anchors and cables used in the merchant navy should be of the best quality. This can only be secured by a public test, under proper supervision, and the bill provides for powers to the Board of Trade to license public testing establishments for this purpose, and to secure proper control over them by seeing that the testing machinery, &c., is kept in proper order, and that the various bodies licensed to erect testing machines carry on their business in an efficient manner. The duties of the Board of Trade, as proposed in the bill, will be very simple, being confined to licensing proper parties, and to seeing, as above stated, that the machinery is in an efficient state for the purpose contemplated. The charges for testing will also be subject to the approval of the Board of Trade; and there is a clause enabling owners of cables or others who may be aggrieved by the conduct of owners of testing machines to memorialize the Board of Trade, who are authorized to make inquiry into the matter complained of. The bill also provides that it shall be unlawful, by a certain date to be fixed, for dealers to sell unproved anchors and cables. The act is intended to apply to all British vessels, propelled by steam or sail, engaged in the foreign, colonial, or coasting trade; and the test to which anchors and cables are to be subjected is the standard adopted by the Admiralty, which has been found to answer, and to secure a very superior article, thoroughly efficient in every way. A parliamentary committee sat in February and March, 1860, under the chairmanship of Sir James Elphinstone, to inquire into the manufacture of anchors and chain cables for the merchant service, and made a report strongly in favour of a compulsory test.

On Saturday last the foundation stone of the new bridge at Blackfriars, was laid by Lord Sondes. This bridge will form part of a connecting link between the London, Chatham, and Dover and the Metropolitan or Underground Railway. A large passenger station will be erected in close proximity to the southern abutment of the bridge. It will be called the "Blackfriars Station." The bridge will have five spans, the centre one being 188 ft., the second and fourth are 177 ft. 8 in., and the first and fifth are 163 ft. span. The abutments will be of brickwork, cased with Portland stone, and the foundations are taken down to the London clay, at a depth of 27 ft. below Trinity high water. The first stone is laid at the level of low-water mark, or 18 ft. below high water. The abutments are built in coffer-dams of the ordinary construction, which are the largest ever executed in this country. The piers, four in number, are of a somewhat novel construction, and the method to be adopted in their erection has never been before attempted. The foundations for the piers will be laid at a depth of 55 ft. below Trinity high water; and in order to get to this depth without the expense and inconvenience of coffer-dams, large wrought-iron caissons, 18 ft. in diameter, are sunk into the bed of the river till the required level is reached, when the brickwork is commenced inside them, and carried up 2 ft. below low-water line. At this point the masonry of the piers commences, and this is laid within a temporary caisson to 5 ft. above Trinity high water. The temporary caisson will then be removed. From this height to the level of under side of girders, the piers consist of clusters of cast-iron columns, of which one will be under each girder; and as there are three girders throughout the length of the bridge, the bridge will consequently consist each of three such clusters of columns. The girders, on the lattice principle, will rest on the tops of the columns, and the headway afforded for navigation will be 30 ft. 3 in. above Trinity high water. The coffer-dam of the north abutment is already in a very forward state. The three large caissons at the first pier on the south side are lowered into the bed of the river, and the divers are now employed sinking them to their proper depths, preparatory to commencing the masonry of the pier. The timber piling staging for the other piers is in a forward state, and will soon be completed and ready for placing the caissons in their proper positions. The bridge is expected to be ready for traffic in May of next year. Messrs. Cubitt and Turner are the engineers; and Messrs. Peto, Brassy, and Co., the contractors.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c., 2754, 2789.
BOILERS AND FURNACES—*none.*
SHIPS AND BOATS, including their fittings, 2759, 2767, 2782, 2797, 2798.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2752, 2753, 2758, 2766, 2776, 2781, 2789.
CULTIVATION OF THE SOIL, including agricultural implements and machines—*none.*
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 2748.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2763, 2764, 2765, 2779, 2783, 2786, 2787, 2792, 2793.
BUILDINGS AND BUILDING MATERIALS, 2746, 2773, 2778.
LIGHTING, HEATING, AND VENTILATING, 2745, 2770.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2742, 2743, 2749, 2750, 2757, 2761, 2768, 2769, 2775, 2777, 2791, 2794, 2796.
METALS, including apparatus for their manufacture, 2760, 2774, 2780.
CHEMISTRY AND PHOTOGRAPHY, 2756.
ELECTRICAL APPARATUS, 2772.
WARFARE, 2744, 2747, 2755.
LETTER-PRESS PRINTING—*none.*
MISCELLANEOUS, 2751, 2762, 2771, 2784, 2785, 2788, 2795.

2742. E. J. Franklin. *A combined spring tape measure, needle case, and pincushion.* Dated October 11, 1862.

The body of this combined instrument consists of a hollow rectangular case or box, in a portion of which the spring tape measure is contained, the said spring tape measure being of the ordinary kind. The pincushion is formed upon a portion of the edges of the said case or box, that part of the interior of the box or case not occupied by the spring tape measure being filled with sawdust, wool, or other material to retain the pins inserted into the pincushion. On the sides of the box or case containing the tape measure and pincushion flaps or covers are situated, one or both of which may open from the case after the manner of the cover of a book. Between the moveable flap or flaps and box or case pieces of fabric are placed, into which the needles are inserted; or openings or recesses may be made in the inner sides of the flaps for the reception of packets of needles. *Patent abandoned.*

2743. A. Vennedy. *An improved composition for covering and forming the tips of umbrellas and parasols, also applicable to covering the ribs and stretchers of the same.* Dated October 11, 1862.

This invention consists in the employment of the following substances for producing a composition suitable for covering or forming the tips of umbrellas and parasols, and for coating the ribs and stretchers of same with a view of ornamenting them. The ingredients employed are paste, sealing wax, shellac, sulphur, varnish (the latter substance may, in some cases, be dispensed with), or substances of a similar nature, or made from a combination of one or more of the same. *Patent completed.*

2744. R. A. Brooman. *Improvements in breech-loading firearms.* (A communication.) Dated October 11, 1862.

This invention relates to those breech-loading firearms in which the Lefaucheux cartridge is used with detonating powder for ensuring central fire, and consists—1, in arrangements of piston and hammer for exploding the cartridge, and for withdrawing the piston; 2, in an improved means of forcing the cartridge extractor to protrude beyond the rear of the barrels upon the same being tilted; and, 3, in an arrangement for extracting the cartridge in single barrel guns and pistols. The exploding piston is hinged or attached by a pin on a horizontal plate, or it is formed in a piece with the plate, which carries on the outer side a projection, against which the face of the hammer strikes to drive forward the piston and explode the charge. The plate also carries a stud or projection farther back than that first mentioned, which lies in a curved slot formed in the side of the hammer. On raising the hammer after firing the gun, the stud and consequently the piston are withdrawn. For forcing the cartridge extractor to protrude the inventor fits on the bolt, on which the barrel and forepart of the stock are free to tilt, an upright plate, formed with a notch on the under part. On the barrels being tilted, the fore end of the back part of the stock coming against the notch on the plate, forces the upper part of the plate forward, which, coming in contact with the fore end of the extractor, causes the rear end thereof to be protruded. For single barrel guns and pistols he makes the barrel to turn upon a pin passed through an aperture in a lump formed in a piece with the rear end of the barrel, and pushes back a hooked rod engaged under the flange on the cartridge; on withdrawing pressure from the rod a coiled spring returns it to its original position. *Patent completed.*

2745. W. Catchpool. *Improvements in fire-escapes.* Dated October 11, 1862.

For the purposes of this invention, the inventor employs a basket or frame adapted to receive the persons about to escape. This basket or frame may be made of metal, or other open work, to give lightness to it, and may have a temporary top, so as to be generally used as a table or sideboard, and it is provided with several chains or cords, by which it may be suspended from a central ring or connection, with one end of a main supporting chain or rope, the other end of which is attached to a spindle which may be applied to the window, or other opening from which escape is to be effected. Upon this spindle is applied a pulley, acted upon by a friction band or brake, so that a person in the place from which descent is to be effected, may, by acting on this friction band or brake, regulate the speed of descent of the basket or frame, or by a separate chain or cord the party descending may regulate the speed of descent. He also forms the spindle from which the chain or cord is unwound in the descent of the basket or frame of a progressively diminishing diameter, from one end to the other, thereby to avoid the tendency to a progressive increase of velocity, arising from the action of gravity during such descent. And he also forms the ribs of the basket or frame curved, and inclining inwards at the bottom, and when it is formed of several sides, the surfaces between the ribs are inclines inwards, by which facility is given in passing cornices or other projections from the surface of the structure. *Patent abandoned.*

2746. J. Durant. *Improvements in the form and construction of chimney tops, or appliances for surmounting chimneys.* Dated October 11, 1862.

This invention consists in forming the chimney can so that its base may be eitheir circular, square, or polygonal; the stalk, or portion above the base, is preferably cylindrical in these parts. The patentee does not claim anything new in form or construction. The upper portion of the stalk is encircled by a corrugated conical cap, the lower end of which, with the corrugations, cover, project over, and encircle the upper portion of the stalk, the upper part of the conical cap being of nearly the same diameter as the stalk, which it also encircles and rises above. On the outside of the upper portion of the conical cap is fixed another corrugated cap of rather smaller dimensions than the last mentioned. The effect of the corrugations of these caps is to form channels on the outside, which causes the exterior atmosphere to rush through the different channels upwards, and in like manner the air, instead of passing downwards, is carried off by the same chamber. Within a small rib or bar over the top of the can is suspended a double conical valve or float; the spindle of the valve passes through an eye or slip in the rib, and allows the valve to rise or fall. When acted upon, the diameter of the valve being less than the top of the can, the smoke reflected from its conical surface passes easily off, and similarly the down draft is carried through the corrugated channels of the comb; the brush, in the cleaning of the chimney, can also pass fairly out at the top, the valve being raised up by it above the level of the mouth. *Patent completed.*

2747. T. Bouch. *Improvements in machinery or apparatus for charging or filling cartridges.* Dated October 11, 1862.

Under one modification this apparatus consists of a metal frame, which can be readily fixed to a bench or table by means of a pinching screw. Extending up from the back part of this frame or base is a bracket which supports a hopper divided into cells for containing the powder and shot to be filled into the cartridges. The supply of powder is placed in each alternate cell of the hopper, and the shot in the intervening cells. The hopper is fixed to a rectangular chamber of a trough-like figure in its transverse section, into which the feed aperture at the bottom of each cell of the hopper opens, and there are openings in the lower part of the chamber which communicate with tubes that serve to convey the powder and shot alternately into the cartridges. The chamber is fitted with a sliding-piece, which has tubular chambers formed in it, corresponding to the number of powder or shot cells contained in the hopper. These tubular chambers have a cubical capacity exactly equal to the measure of powder or shot required for each charge, and are so arranged that, when the sliding-piece is drawn to the right, for example, the chambers are brought under the powder cells, and the powder falls into the sliding-piece, and into the tubes beneath. The escape of the shot is meanwhile prevented by the solid face of the sliding-piece being beneath the apertures of the shot cells. The movement of the sliding-piece to the left shuts off the powder cells, and brings the tubular chambers under the shot cells, which now descend into the tubes. The quantity of powder and shot thus fed into the tubes is regulated by the size of the chambers and tubes, so that the cartridges filled by means of the machine are exactly uniform in this respect. The paper cartridges to be filled are placed in vertical cells formed for the purpose in the front of the base piece or main frame in a vertical line with the powder and shot tubes, and are enclosed by a hinged door-piece, which is fastened by a catch during the filling operation. At the back of the hopper are arranged two or other number of vertical tubes for containing the wads to supply each cartridge as it is filled. These tubes are each fitted with a spring presser to force down the wads, and they are brought forward over the cartridges by means of duplex sliding-pieces, which are arranged to bring the thick and thin wads alternately into the cartridge. The thick and thin wads are arranged alternately in the feeding tubes, so that when the charge of powder has been allowed to fall into each cartridge, the duplex slide is pulled forward, and draws a thick wad over the cartridge. The powder and wad is rammed down by means of the filling tubes, which are made moveable, and connected to a cross-head having laterally projecting handles, and working on vertical guides. The operator depresses the cross-head, which causes the tubes to descend and drive the wads down upon the powder. The cross-head and filling tubes are kept up firmly to the chamber below the hopper by helical springs surrounding the guides, or by other equivalent means. The duplex and slide is pushed back, and the charge of shot filled into each cartridge by shifting the filling slide to the left, and the lower plate of the duplex wad slide is drawn out, which brings a thin wad over each cartridge, and these wads are pressed down on the shot by means of the cross-head. The final operation is to roll in the end of each cartridge so as to prevent the escape of the wad and contents. *Patent completed.*

2748. A. V. Newton. *Improvements in evaporating apparatus applicable to the manufacture of sugar.* (A communication.) Dated October 11, 1862.

In constructing evaporating apparatus according to this invention, the bottoms of the pans or boilers are made with corrugations sufficiently deep to form flues running longitudinally along the boiler for the passage forwards of the flame and heated gases of the furnace, and between these flues channels for the circulation of the liquid under treatment. The boiling vessels may be arranged in the ordinary manner employed in the colonies. *Patent completed.*

2749. A. V. Newton. *Improvements in sewing machines.* (A communication.) Dated October 11, 1862.

This invention consists in providing the means whereby the use of the ordinary shuttle may be dispensed with, and the consequent necessity of rewinding the thread removed, while at the same time a regular shuttle stitch, alike upon both sides of the cloth, and of an elastic character, is produced. The invention further comprises a means for giving the requisite motions to the feed by the use of a spring cam feeding device, which is much stronger, and at the same time more simple and less liable to get out of repair than those in ordinary use. This invention cannot be described without reference to the drawings. *Patent completed.*

2750. S. Chatwood. *Improvements in, and connected with, fire and thief proof depositories, and locks or fasteners connected therewith, parts of which improvements are also applicable to other purposes of security.* Dated October 11, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2751. G. and A. Harvey. *Improvements in boring machinery.* Dated October 13, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2752. A. F. Gallis. *Covering street omnibuses and vehicles of every description for the purpose of sheltering passengers travelling on the top of the same.* Dated October 13, 1862.

In carrying out this invention, the iron rails are higher than usual, the actual height of them being still increased by a curtain which passes all round the omnibus. When bad weather comes on, the conductor requires only a few minutes to raise the cover, and a still shorter time to let it down, together with the upper rails, after the rain has ceased. Lateral openings in the cover serve to check the action of the wind. These openings can easily be closed and opened again by the passengers. The invention further consists in a mechanical contrivance by which a number of solid iron or other bars, contained within iron or other tubes, may, by means of chains, &c., worked over rollers with a handle within easy reach of the conductor, be raised to the proper height to support the covering or awning. The water-tight covering or awning lies folded up in fine weather behind the driver's seat. When required for use, the conductor simply draws a string attached to the cover, which then glides easily over the bars by means of rings or otherwise. When it is no longer required, the driver pulls it back by another string behind him. *Patent completed.*

2753. G. Haseltine. *Improvements in "jacks" and screw nuts for attaching thills and poles of waggons and other vehicles to the axletrees of the same.* (A communication.) Dated October 13, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2754. C. McCarthy. *Improvements in automatic safety valves.* Dated October 13, 1862.

This invention consists in the arrangement of a safety valve attached to a steam boiler, which will be acted upon by the water in the boiler, and will operate either when the pressure of the boiler becomes equal to or shall exceed the load on the valve, or will act in combination with a water indicator whenever the water in the boiler falls to a certain point below the fixed water-level in the boiler, the said valve being connected with the water in the boiler, and with the fire-place, so that in either case, and whenever the valve is raised, the water from the lower part of the boiler will be forced through the safety valve and thrown into the fire-place, so as to damp or extinguish the fire, and thereby prevent or remove all further danger. Whenever the improved "automatic" safety valve operates on account of an excess of pressure in the boiler, the water will be thrown into the fire-place upon the fire, so as to dampen the same, thereby diminishing the heat, and consequently the pressure in the boiler, when the valve closes again, and the fire will readily rekindle. When the valve operates in combination with the water-indicator on account of a deficiency of water in the boiler, the water will be thrown upon the fire as long as it continues to fall in the boiler, which will soon extinguish the fire altogether, preventing thereby any overheating of the fire-plates, and consequently avoid all further danger. The water-indicator, which operates the safety valve whenever the water in the boiler falls to a certain point below the fixed water-level, is so constructed as to operate independently of the safety valve as long as the water-level is above the fixed point, and acts then as an indicator to show the position of the water-level in the boiler; and only when the water falls below that point which may be considered dangerous the same will act upon the safety valve, so as to raise the same, and cause the water to be forced upon the fire to extinguish the same, and prevent thereby any further accident. *Patent completed.*

2755. W. Loeder. *An improved projectile to be used with ordnance or firearms of any calibre.* (A communication.) Dated October 13, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2756. C. Thomas. *Improvements in the manufacture of silicate of potash, and in the manufacture of artificial stone.* Dated October 13, 1862.

In the manufacture of silicates of soda, or of potash, it is usual to digest the silica with the potash or soda in a close boiler, in which mechanical stirrers have in some cases been arranged. According to this invention, the patentee mounts the boiler so that it can rotate or oscillate. The boiler is kept in motion during either the whole or a portion of the time occupied in the process of solution, and in this manner there is produced a friction between the several particles of silica sufficient to rub off the gelatinous coating formed by the action of the caustic alkali on the same, and thus the process of solution is greatly facilitated, clean or fresh surfaces being constantly presented to the action of the soda or potash. He prefers to use a jacketed boiler heated by steam rotating or oscillating horizontally. In manufacturing artificial stone, he combines a solution of silicate of soda with the refuse produced in the process of alkali making, and commonly known as "black ash waste," or with "burnt iron pyrites," ground or pulverized, or with a mixture of these two materials. The black ash waste and burnt iron ore will, when mixed either separately or conjointly with silicate solution, form a hard stony mass, and the composition whilst soft may be moulded into any desired form, or made into large or small blocks, suitable for building or other purposes. *Patent completed.*

2757. W. G. Haig. *A new article of apparel to be worn instead of, or in addition to, shirt front and waistcoat.* Dated October 13, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

2758. J. Gumbley. *An improved break for vehicles travelling on common roads.* Dated October 13, 1862.

The object of this invention is the construction of apparatus in such manner that the power or pressure exerted by a horse (or other draught animal) in keeping back a vehicle in descending a hill or incline shall be so transferred or transmitted as to force a break on to or against the wheel. This may be effected as follows:—The breeching or other means on which the horse (or other draught animal) acts or presses to keep back the vehicle (when descending a hill or incline), instead of being attached to the shaft or pole, is attached to a chain or strap, or to chains or straps; such chain or strap, or each such chain or strap, runs round a pulley fixed on the under part of the shaft, or at the end of the pole, or in such like position, and thence passes to the end of a lever which works on a pin or axis at the oposite side of the vehicle; this pin or axis is fixed through the shaft, or in other convenient part, and the lever carries the break block, skid, or similar contrivance. When the horse applies pressure against the breeching or other means on which it acts for keeping back the vehicle, the levers will be thereby worked, and will bring the break-blocks, or other equivalent contrivances, into action. *Patent completed.*

2759. A. J. MAHON. *Improvements in propellers and paddle floats, also applicable to the raising and forcing of water or other fluids.* Dated October 13, 1862.

This invention relates to new forms of screws and screw-blades, and their combination and arrangement, so that the vacuum caused by the ordinary working and their different currents may be taken advantage of, and so that the centres of all screws may be made to work effectively, and get rid of centrifugal force and lateral loss. *Patent abandoned.*

2760. E. B. WILSON. *Improvements in apparatus employed in the manufacture of iron and steel.* Dated October 13, 1862.

This invention consists in the employment of a valve, stop-cock, or other suitable contrivance applied to the blast pipe or pipes of the atmospheric vessels, or of blast furnaces, employed in the manufacture of iron and steel, for the purposes of throttling or wire drawing the blast before entering such vessels or furnaces, and producing in reality a blow-pipe action, by reason of the tensity of the entering jet or jets of air, steam, or gas injected. *Patent completed.*

2761. S. SMITH. *Improvements in kettles, saucepans, and boilers for domestic and other purposes.* Dated October 14, 1862.

This invention consists in having a tube or tubes of suitable form from the bottom of the kettle, saucepan, or boiler, and terminating at the back, sides, or any part that is most suitable. The inventor likewise proposes making an arch from the bottom of the said kettles, saucepans, and boilers, starting from the bottom, and terminating at the back or sides, the object being to boil the water or liquid in detail. *Patent abandoned.*

2762. F. G. GRICE. *An improvement or improvements in the manufacture of nuts for screwed bolts, and in machinery to be employed in the said manufacture.* Dated October 14, 1862.

This invention consists in manufacturing nuts for screwed bolts at one heat, that is to say, by taking nut iron direct from the rolls and subjecting it without reheating to the treatment proper to convert it into nuts. By this invention the deterioration in the quality of the iron caused by reheating is prevented, and the nuts are produced of a uniform thickness. In carrying the invention into effect, the patentee rolls iron of the proper shape and size in suitably constructed rolls, and as the heated and shaped iron comes from the rolls he cut it into short lengths, by means of a circular saw, or by a pair of shears, the said lengths being of such a size as to enable the workman to hold them easily with a pair of tongs. He feeds these short lengths of nut iron into a machine working at a quick speed, cutting off the nuts from the nut iron, and shaping and punching the nuts while the iron retains sufficient heat for these purposes. The machine or machines which he employs for converting the nut iron into nuts have, essentially, the same construction and action as ordinary machines, but the parts are made to work with a quicker speed. *Patent completed.*

2763. E. LUCKOW and E. HABEL. *Certain improvements in machinery or apparatus for preparing, spinning, and doubling cotton and other fibrous materials.* Dated October 14, 1862.

This invention relates to a novel description of machinery for twisting slivers or threads, or for doubling slivers or threads together, and simultaneously winding them upon bobbins; and the invention consists in a novel arrangement and adaptation of mechanism, which may be described as follows:—The sliver or single or doubled yarns pass from drawing rollers through a trumpet mouth, and thence through a guide or eye upon a sliding block, which delivers the yarn to the bobbin. This slide has a reciprocating traversing motion imparted to it by means of a right and left-handed screw, so as to distribute and lay the yarn evenly upon the bobbin; and in its traverse it acts upon a double-inclined plane, causing it to rise and fall in such a manner as to take up or compensate for the slack yarn which passes over it, and which arises from the different length of yarn between the ends and the middle of the bobbin. On the opposite side of the bobbin or fluted roller is placed, their peripheries being parallel, and kept in contact by means of annular springs pressing upon the bearings of the bobbin, which receives a rotary motion from the said rollers causing the winding on of the yarn. The speed of this fluted roller, and, consequently, the amount of twist in the yarn, is regulated and governed by a differential motion, which is effected by simple arrangements of bevel gearing or worm and worm-wheel, or other equivalent gearing driven from a continuous driving shaft provided for the purpose, and extending from end to end of the machine. This apparatus, excepting the differential motion, is arranged in a framework, in order to impart the twist to the yarn. The frame carrying the bobbin and fluted roller is caused to revolve between bearings by means of band and fast and loose pulleys attached to the frame, so that the bobbin is caused to revolve across its axis (end over end) as well as parallel thereto, by which means the twist and draw are effected simultaneously. *Patent abandoned.*

2764. H. BRIDSON and J. ALLCOCK. *Improvements in machinery for folding, measuring, and hooking woven fabrics.* Dated October 14, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2765. E. BARLOW, J. CLOUGH, and F. HAMILTON. *Certain improvements in machinery for driving cotton gins, and for preparing and combing cotton and other fibrous substances.* Dated October 14, 1862.

This invention consists in supporting the axles of the driving and fly-wheel shaft on anti-friction rollers, and in placing anti-friction rollers on each side of the said axles, by which means the friction, and, consequently, the power required for driving, are much reduced. Similar anti-friction rollers are or may be applied to the axles of the roller of cotton gins. The improvements in machinery for preparing cotton and other fibrous substances are applicable to slubbing frames, roving frames, and other machines of the like description, and consist in the application to such machines of additional wheels to the wheels now employed for transmitting the motion from the differential wheels to the spindles, by means whereof the irregularities in the taking up of the bobbins are prevented. The improvements in machinery for combing cotton and other fibrous substances is applicable to the circular combing machines, and consist in making the weight by which the sliver is held in the guide spout with two projections fitting in slots in the sides of the spout; these slots have each a shoulder or set off, so that, when the weight is in its place, it cannot be displaced by the extra depth of the sliver, or by the moving of the spout. *Patent completed.*

2766. J. SNIDER. *Improvements in the construction of "Hansom cabs" and other similar vehicles.* Dated October 14, 1862.

This invention consists in the application to the forward part of the top or front of the vehicle of a folding or moveable cape or curtain, sustained by a frame, and which can be projected or retracted at pleasure, and which is primarily destined to serve as a protection from the weather in lieu of the present inside folding glass or framed shutters or flaps, called "the glass," but also as a sun shade. *Patent completed.*

2767. C. HARRATT. *Improvements in ships' masts.* Dated October 14, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2768. D. and C. J. REID. *Improvements in the manufacture of cases for watches and other time-keepers.* Dated October 14, 1862.

This invention consists in the manufacture of cases for watches and other pocket time-keepers of the alloy or compound of copper and aluminium hereafter described:—The patentees believe that the best compound or alloy for the purpose consists of 92½ parts of the best copper, and 7½ parts of aluminium; this alloy possesses a good gold colour, and has good working qualities. The proportions of the alloy may, however, be somewhat varied. *Patent completed.*

2769. M. CARTWRIGHT. *Improvements in plates for artificial teeth.* Dated October 14, 1862.

This invention consists in combining leaf gold, or finely precipitated gold with india rubber or gutta percha, for the purpose of forming plates for artificial teeth. The patentee first dissolves the india rubber or gutta percha, and grinds the gold leaf with the same, in order effectually to combine the metal with the gum used. He afterwards heats this compound to render it plastic, and shapes the plate by working it over or into a mould or model of the plate to be produced. The invention further consists in forming plates of a combination of sulphuret of zinc and kaolin, which, after being reduced to a liquid state, is applied in successive layers upon the model of the plate to be produced, until a sufficiently thick plate composed of such layers is formed. In some cases, for affording additional strength to the plates, he introduces some fibrous material or metal gauze. *Patent completed.*

2770. R. A. BROOMAN. *Improvements in apparatus for carburetting gas.* (A communication.) Dated October 14, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2771. R. A. BROOMAN. *Imprvements in dressing millstones, and in materials employed therein.* (A communication.) Dated October 14, 1862.

This invention consists, essentially, in dressing millstones by the action of hydro-fluoric acid on the silicious matter of which the stones are more or less composed. *Patent abandoned.*

2772. E. H. C. MONCKTON. *Improvements in coils of inductions, and in obtaining and applying power by means of electro-magnetism.* Dated October 14, 1862.

We cannot here quote the voluminous details of this invention. *Patent completed.*

2773. O. J. and J. SHOWELL. *Improvements in the construction of glass roofs and roof lights.* Dated October 14, 1862.

This invention relates to a mode of constructing glass roofs or roof lights in such a manner as to render them water-tight, without the use of putty or cement, and so that they may be capable of giving way to slight movements arising from expansion and contraction, and from other causes; and the invention consists in the use of glass sheets or plates, with their two opposite parallel edges turned at right-angles or thereabouts to the plane of the sheet or plate, and in arranging such sheets or plates so that their turned edges will come together, the edges being placed either up or down; if upwards, they are covered with a cap; if placed downwards, they enter a gutter, the caps or gutters being made of metal or other suitable material. *Patent completed.*

2774. S. HEALEY. *Improvements in the manufacture of zinc.* Dated October 14, 1862.

This invention consists in constructing the furnaces employed in the melting and annealing of zinc in close proximity to each other, so that the process of annealing may be effected by means of the waste heat escaping from the melting furnace. *Patent abandoned.*

2775. J. H. JOHNSON. *Improvements in sewing machines.* (A communication.) Dated October 14, 1862.

This invention relates to a peculiar construction and arrangement of sewing machine suitable for button hole, or edge-finishing, or stitching. In this machine the vertical needle bar or carrier has a lateral motion imparted to it by a cam, for the purpose of causing the vertical needle to pass alternately through and over the edge of the material operated upon. The up and down motion of the needle bar is obtained from a crank pin in a disc on the front end of a driving shaft working in a slotted piece attached to the needle bar. The cam shaft is placed vertically, and receives its motion from the driving shaft by means of a bevel wheel and pinion, it making one revolution for two of the same shaft. A loop carrier operates beneath the table, being connected by a bar with a suitable cam on the vertical main shaft. The detailed arrangements as described in the specification are very voluminous, and cannot be given here in full. *Patent completed.*

2776. E. MOLYNEUX. *An improved carriage with a travelling railway attached.* Dated October 16, 1862.

This invention consists essentially in the construction of a carriage so related to and connected with two short lines of rails, that it shall change from one to the other by the revolution of its wheels, without the rails being required to move either laterally, diagonally, or vertically, and that a portion of its moving force shall be employed to shift successively each line of rails as it becomes free, to a position on the ground over which the carriage will have to travel immediately on leaving the rails on which it is bearing, and so to form a continuous travelling railway of two short and independent lines of rails. *Patent completed.*

2777. W. WILSON. *An improved oblong drawing-room, bagatelle, and billiard table with reversible top, and made in various shapes and sizes.* Dated October 15, 1862.

This invention consists of an oblong drawing-room, bagatelle, and billiard table, so constructed that the game is on one side, and by reversing the top it forms a drawing-room table, made oblong, oval, circular, and other shapes, and in various sizes. The peculiarity of this invention is the compactness of the table, that side on which the game is played being concealed in the frame when shut, and the top has only to be turned over when the game is required to be played. That side of the table on which the game is played has a channel or rim on both sides, or may be with a groove, bridge, or tunnel enclosed. *Patent compteled.*

2778. J. H. JENKINSON. *Certain improvements in drinking fountains.* Dated October 15, 1862.

This invention consists in applying to drinking fountains tubes through which water is drawn into the mouth of the drinker by suction. *Patent completed.*

2779. J. TAYLOR. *Improvements in temples for looms.* Dated October 15, 1862.

In carrying out this invention the patentee gives to and fro motion to revolving combs working loosely at one end in an concentric slot, and at the other end in an eccentric slot, both of which slots are held stationary in the temple head. As the combs or teeth revolve they project one after the other beyood the periphery of the roller which contains them, and thus catch the fabric as it is woven, and keep it extended to its proper width, and where necessary, as in woven fabrics, give it an extra stretch in the transverse direction. Each set of combs or teeth holds the fabric in its extended position until the succeeding set takes hold, and all the combs recede one after the other in the grooves of the roller which contains them. *Patent completed.*

2780. C. DE BERGUE. *Improvements in the apparatus for the crushing and treatment of ores.* Dated October 15, 1862.

Provisional protection has not been granted for this invention.

2781. C. DE BERGUE. *Improvements in the permanent way of railways.* Dated October 15, 1862.

This invention has more especial reference to further improvements upon a certain description or descriptions of permanent way, and of certain parts thereof, in respect of which letters patent were granted in 1853 (No. 1245), and in 1861 (No. 2616), namely, the permanent way or ways in which the rails rest upon and are held in cast-iron chairs or cast-iron sleepers, without upright bags or jaws, but are secured to each such chair or sleeper by a clip piece, and by one bolt or fastening only. Now whereas in such permanent way or ways the arrangements have been such as to accommodate flat-bottomed rails, he now proposes to accommodate double-headed rails. The present improvements consist—1, In forming the chair or the sleeper with seating for the rail of a form corresponding with the section of the double-headed rail, or nearly so, but, as above stated, without the common upright lugs or jaws, such seating providing a lateral abutment for the inner side of the lower head or member of the rail. 2, In forming the clip piece so that it shall not only press upon the upper side of the lower head or member of the rail to prevent the rail rising or jumping, but shall also present an abutment or resistance against which the web of the rail shall bear to maintain the rail in the intended upright or nearly upright position, and so prevent its tilting or tumbling over the tail of the clip piece itself; also taking a lateral abutment against the chair or sleeper. And, 3, The use of the foregoing in combination with a double-headed rail and a single bolt with each clip piece to form permanent way. *Potent completed.*

2782. W. POPE. *Improvements in coating the sides of ships, batteries, forts, or other places with defensive armour plates.* Dated October 15, 1862.

The patentee claims applying to the hulls of ships, floating batteries, or land forts, plates, sheets, or shelves of metal and timber combined, or of metal and any other substance combined, in such wise that one edge of such plates of metal, or metal and timber, or metal and any other substance, shall be outermost to receive the shock of the shot, shell, or other projectile. *Patent completed.*

2783. P. Potenza. *The extraction, preparation, and spinning of the silky fibre contained in the bark of mulberry trees, and the manufacture of the same into textile fabrics.* Dated October 15, 1862.

This invention is carried out as follows:—The bark, after careful separation from the wood, is subjected to a process of thorough desiccation, which process should take place very gradually, by preference in the open air, and under very moderate action of the sun, as otherwise the bark would not form the so-colled "maca," and the fibrous substance which it is desired to extract would be totally destroyed. When the bark has been thoroughly dried, the fibrous substance which will then be found in the same in the form of agglomerated filaments of an exceedingly fine texture, is carefully extracted by separating from it all extraneous matter that will be found adhering to it, such as the epidermis, the green bark or rind resembling a skin, and the liber, whenever this is found next the sap (as it is not always there). This separation of the silky fibre from the various layers of bark, and from all other substances by which they are held cemented together, to a certain extent, is effected most readily by boiling the bark either in water alone, or with the admixture, by preference, of a mineral acid, or of a vegetable alkali, combined with the base of an oil or fat; or the patentee sometimes employs a mineral alkali, or even vegetable acid, for this purpose. By this means the masses of fibres or filaments are not only freed from all extraneous matters and impurities, but are rendered exceedingly soft, and capable of being separated from each other in the most perfect manner. The fibres are finally opened out, carded, formed into slivers, and the doubling and stretching effected by ordinary machinery. *Patent completed.*

2784. J. B. G. M. F. Piret. *Improvements in lubricating apparatus.* Dated October 15, 1862.

This invention relates to an improved oil box, or that of any other liquid or lubricating apparatus for lubricating all kinds of axles, and especially railway carriage axles, the characteristics of which are—1. A continual rise and spread of the liquid obtained from a lower reservoir over the surface of the axle. 2. A partition placed at the lower part of the axle box, which prevents any escape of the liquid at back of the reservoir, caused by the motion of the vehicle. 3. An improved coupling or stuffing box, fixed behind the journal, which prevents all lateral spread of the liquid from the box along the axle. 4. The application of a guard plate for preventing the introduction of any foreign matter into the box. The invention cannot be described without reference to the drawings. *Patent completed.*

2785. F. F. Prud'homme. *Improvements in machinery or apparatus for raising water.* Dated October 15, 1862.

This invention consists of two main portions, one of which the patentee calls the lift pump, and the other the driving or force pump. The lift pump is placed nearly at the bottom of the well, shaft, or other place whence water is to be lifted. The force or driving pump is outside such well, shaft, or place, and close to the steam or other driving engine or motive power employed, whatever be the distance of such engine or power from the mouth of the said well, shaft, or place. The two portions, that is, the lift pump pump and the driving or force pump, communicate by means of one or two strong and staunch pipes, through which the water rises, such pipe or pipes opening at bottom into the lift pump, and at their further end into the driving pump. The lift pump is a cylinder or barrel, closed at the ends, and fitted with two equal solid pistons on the same rod. This cylinder or barrel is divided endwise by a solid partition or diaphragm, through which the rod of the pistons passes, the rod working through a stuffing box. Suction and force pumps are provided. The force or driving pump consists of a cylinder or barrel fitted with a solid piston worked by a steam or other engine or motive power, and the to-and-fro motion of this piston is transmitted to the pistons in the lift pump by the water in the ascension pipes. The force pump piston is connected to the steam or motive engine by jointing the pump piston rod to the crank arm or beam of such steam or motive engine. The lift and force pump cylinders are bored and formed smooth and true on the inside. The lift pumps may most conveniently be fitted three or four yards above the surface of the water to be raised. *Patent completed.*

2786. J. Bapty. *Improvements in apparatus for preparing wool and other fibrous materials.* Dated October 15, 1862.

For the purposes of this invention a conical drum is used mounted on axes; and on the surface of this drum are teeth, which are, by preference, set in spiral lines. The drum revolves within a case, and there is a rocking bar (or bars) applied from end to end of the case. On this bar or bars there are teeth which, on the rotation of the conical drum, come between the teeth on the drum. The bar or bars have a rocking motion applied thereto, so that the teeth thereon are moved or swung to and fro. At the under part of the case of the drum is a chamber to which a fan or exhausting apparatus is applied, so as to produce a slight current from the chamber towards the fan, sufficient to remove the dust as it passes through a partition which is placed between the exhauster chamber and the chamber within which the conical drum revolves. This partition is made with bars, or is otherwise made reticulate, so as to admit of the dust passing through, whilst the fibrous matters which are being acted on are prevented passing through the partition. The fibrous matters which are to be opened out or mixed, and thus prepared for the subsequent process of carding or otherwise, are fed in at the side of the case of the machine near the smaller end of the conical drum, the feed extending along only a portion of the length of the conical drum. As the fibrous substances are more and more thrown and beaten in the machine, they will progressively be moved from the smaller end towards and out of that end of the case where the larger end of the drum is situated, which is open for the purpose of permitting the fibres as they come to the larger end of the drum to be thrown off therefrom through the open end of the case. *Patent abandoned.*

2787. R. A. Brooman. *Improvements in felting machines applicable also to the fulling, scouring, and dressing of pure and mixed woollen stuffs.* (A communication.) Dated October 15, 1862.

These machines are intended specially for the production of felted threads, but they apply also to the fulling, felting, scouring, and dressing with heat and moisture of pure or mixed woollen stuffs. In the machine two frames carry the felting rollers arranged in two series, one series revolving above and between the other series. Alternate rectilinear motions are simultaneously imparted to both frames, while an endless apron and the rollers are made to rotate. The machine is composed of a frame carrying bearings for supporting a main shaft, upon which four eccentrics are fitted which turn in collars, and rods from these collars are jointed to two frames; these frames carry the felting rollers, and are supported upon rods which are free to slide to and fro in bearings on the frame of the machine. Rotary motion is communicated through a bell to pulleys on the main shaft, whereby the eccentrics impart rectilinear to-and-fro motions to the frames, and, consequently, to the two series of rollers carried by them. An endless apron is carried over the under rollers between them and the upper rollers and round stretching rollers. The felting rollers may be clothed to facilitate adhesion of the threads being felted. The apron is driven by ratchet and bevel toothed-gear, and its speed of rotation may be increased or diminished as desired. Spaces are formed between the fronts of the two frames for the entrance of the threads which, coming from cans or bobbins, pass between the apron and upper rollers, and issue through another space in the back of the frame to be wound on a reel. As it is necessary that no very great pressure should be exerted upon the threads, in order to their being round and even, and as only slight friction is requisite, the upper rollers revolve in open topped bearings; and this arrangement facilitates their removal when necessary for passing the apron over the lower series of rollers. When required to impart a differential movement to the rollers, the inventor gears them by toothed-gear and endless chains calculated to produce the speeds required. To assist the felting a steam jet, as generally used, is introduced in the ordinary manner. The apron and the upper series of rollers may be covered with sponge to impart thereto a certain degree of elasticity favourable to the operation of felting. *Patent completed.*

2788. R. A. Brooman. *Improvements in refrigerating and freezing, and in apparatus employed therein.* (A communication.) Dated October 15, 1862.

This invention consists in cooling or freezing in vacuo by the abstraction of heat owing to the evaporation of a volatile liquid, such as bi-sulphide of carbon, ether, or other volatile liquid, contained in a space surrounding the the vessel in which the substance to be cooled or frozen is placed, as well as by condensation of the vapour arising from the substance cooling or freezing, and this in an apparatus constructed and working substantially as described with reference to the drawings. *Patent completed.*

2789. E. A. Cowper. *Improvements in steam engines.* Dated October 15, 1862.

The present improvements have for their object the maintaining more uniformly the temperature of the steam during its action on the pistons; and the invention consists in constructing for this purpose a steam-jacketed reservoir of the following arrangement:—The patentee constructs a steam-jacketed reservoir, having a lining of metal inside it, placed at a small distance from the sides, which lining has a large opening in it, through which the steam enters into the central space without coming into very extensive contact with the steam-jacketed sides of the reservoir, whereas, on the contrary, when the steam is withdrawn from the reservoir, it is caused to pass through a hole or holes in the lining at one part, and to pass between the lining and the steam-jacketed sides of the reservoir for some distance before it leaves it, so that as far as possible it should be maintained at the temperature at which it left the boiler. Or the reservoir is made of any other form composed of cylinders, tubes, or plates, with a space or capacity for the steam to enter it freely without coming into extensive contact with the steam-jacketed parts, and then is so arranged that the steam on leaving does come into contact with such parts, so that as far as possible it should be maintained at the temperature at which it left the boiler. This mode of constructing a reservoir with a space or capacity into which the steam may enter freely from the first working cylinder, whilst means are provided for maintaining it as far as possible at the temperature at which it left the boiler as it leave; such reservoir, is applicable to engines in which either natural or superheated steam is used. *Patent completed.*

2790. W. Barningham. *Improvements in the permanent way of railways.* Dated October 16, 1862.

This invention consists in making railway sleepers, when either transverse or longitudinal, of wrought iron rolled to a semi-elliptical or other suitable form, to combine strength with lightness, and of sufficient area to be firmly supported in the ballast. The rails are attached by bolts or otherwise to chairs or half-chairs, which are welded, riveted, or bolted to the sleepers; or the chairs may be formed of strips of metal cut from the top of the sleeper on three sides, and bent into the required form to suit the shape of rail. When bridge or other flat-bottomed rails are employed they may bear upon and be connected to the sleepers by bolts or rivets. *Patent completed.*

2791. G. Berry. *Improvements in locks.* Dated October 16, 1862.

This invention comprises improvements in that description of lock in which a number of sliding guards pass through notches in a locking plate also having notches in it. In ordinary locks of this description these sliding guards move in grooves by the direct action of a key or instrument, and there is no impediment to an instrument or picklock being inserted in these grooves in such a manner that an operator is able to detect in what part of each sliding guard the notch belonging to that particular guard is placed. The first improvement consists in cutting notches in the sliding guards at right angles to the notches which have to pass the locking plate. He then places an immoveable mask or partition in each of the first named notches, and these masks or partitions consist of rings placed in a barrel; or a plain plate placed in a box, when the motion intended to open the lock is lineal, instead of circular. The result of this arrangement is that the notches in the guards cannot be got at by any instrument whatever, as they are placed in a line parallel to the part acted upon by the key, but separated by masks or partitions. The second improvement consist in cutting the sliding guards into two parts, in such a manner that, if force be applied to one part, that force will be communicated to the other, and both will move in the same direction. These parts through which force and motion are communicated to the other parts are called media. The result is that no vibration of such parts which indirectly receive force and motion is communicated to any picklock or instrument applied to open the lock, whereas in ordinary locks of this description vibrations occur in the sliding guards which distinctly convey to an expert attempting to pick the lock the precise position of the notch where the sliding guard is placed, and by repeating this operation upon each guard he will be enabled to make a key which will open the lock. *Patent abandoned.*

2792. G. T. H. Pattison. *Improvements in machinery or apparatus for embossing or finishing woven fabrics.* Dated October 16, 1862.

The patentee claims obtaining an improved diagonal silk finish upon woven fabrics by using an embossing roller of a single thickness, or with a shell or surface of iron or steel. *Patent completed.*

2793. G. T. H. Pattison. *The imparting of an improved surface or appearance to fabrics woven with mixed materials.* Dated October 16, 1862.

The patentee claims producing a new and improved surface, appearance, or finish upon woven fabrics, by subjecting mixed fabrics woven with cotton warps and worsted weft to a "slash" engraved roller, the impression due to which is retained only or chiefly by the cotton, as described. *Patent completed.*

2794. H. A. Remiere. *An improved horse collar.* Dated October 16, 1862.

This invention consists in replacing the ordinary materials used for stuffing horse collars, such as hay, straw, and curled hair, by two or more cushions or pads of prepared india rubber, filled with air, and so constructed that the india rubber of which the cushions are made is not distended, nor the air with which they are filled in so compressed a state as in those of the air collars at present known. The advantage of this is, that the air is not liable to escape, and the collar retains its form and firmness, yielding only sufficiently to make it comfortable for the horse to pull against. *Patent completed.*

2795. F. Delmas. *A rain absorber.* Dated October 16, 1862.

This invention consists of a band formed of sponges, and is intended to prevent the rain running down from hats, caps, umbrellas, and other articles round which it is placed, and to protect the bearer or persons near him from water pouring down therefrom. The dripping rain is completely absorbed by the sponges of which the absorber is formed. *Patent abandoned.*

2796. T. G. Harold. *Improvements in locks.* Dated October 16, 1862.

The shell containing these improvements, when in the form of a padlock, is secured together by means of flanges formed on each of the side plates of the said case, and the said flanges have screws cut thereon, so that one will screw into the other; the shackle passing through these flanges prevents the lock from being taken apart when locked. To hold the shackle or bolt when locked, the inventor employs circular tumblers, with flanges turned up or formed around the edges, and the said flanges should be provided with teeth or decoy notches on the inner side, and a slot through each flange, so that a shackle or bolt provided with the proper projections will be retained by the flanged tumblers, and the said projections taking into the decoy notches in the flanges of the tumblers, to prevent any person from finding out the position of the slots in the flanges that pass the projections of the shackle or bolt in unlocking. These flanged tumblers are placed one inside of the other, and are connected by solid and pipe-shaped arbors to dials or pointers on the outside of the lock plates, and by setting these dials or pointers to the proper positions, the slots in the tumblers will all be in a line, so that the shackle or bolt will pass outside. The change of combination is effected by placing the flanged tumblers in a different position to the dials or pointers. *Patent abandoned.*

2797. E. Humphrys. *Improvements in steering apparatus.* Dated October 16, 1862.

This invention consists in so combining apparatus for acting by hydraulic power on the rudder of a ship or vessel, that the hydraulic cylinder and other apparatus intermediate of it and the rudder may be all below the line of floatation, and, consequently, out of the way of shot. For this purpose, an arm or projection is fixed to the rudder sufficiently below the water line to protect it from shot. This arm is suitably connected to the piston-rod of the hydraulic cylinder, which is also situated below the water line of the ship or vessel. A stuffing-box is formed through the stern of the ship or vessel for the passage of the piston-rod, or of a connecting rod, so that the communication between the piston of the hydraulic cylinder and the rudder may be water-tight. The arrangement for working the hydraulic pumps and apparatus may be according to the means at present in practice, or otherwise. *Patent completed.*

2798. H. Ransford. *Improvements in building ships and other vessels.* Dated October 16, 1862.

This invention has for its object improvements in the formation of ships, boats, and other vessels, specially with reference to that part between the extreme beam and the stem known as the bows of a ship. For these purposes, in building a ship or vessel, the actual floor and bottom of the ship or vessel is to be constructed wider at the extreme beam, and so as to extend as far or farther forward, and laterally, than the horizontal section taken at the water line when loaded. It is preferred that the floor should extend as near the stem or most forward part of the bow as practicable. The peculiarity of the invention consists in carrying the floor of a ship or vessel, whether flat or with more or less dead rise laterally beyond a perpendicular dropped from the outside of the timbers at the water line, so that the ribs or side timbers slope upwards and inwards from the floor timbers to the deep-load water line, or beyond, as advisable. A ship may advantageously be constructed on this principle even one-fourth or more wider at the floor or bottom than at the deep-load water line at the extreme beam, but whatever slope or angle is adopted at that part it should be diminished. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated Dec. 20, 1862.

3410. W. Perkins, Churchfield House, Margate, Kent, consulting chemist. Improvements in the manufacture of a substitute for turpentine, which is also applicable to the manufacture of varnishes, and to purposes to which turpentine is now ordinarily applied.

Dated Jan. 24, 1863.

218. E. Shackleton, Loth, near Ruysbrook, Belgium, overlooker. Improvements in looms for weaving.

Dated March 14, 1863.

697. W. Young, 77, Fleet-street. Improvements in type composing and distributing machines.

Dated March 20, 1863.

742. W. Reay, jun., Thropton-hill, near Rothbury, Northumberland, mining engineer. An improved machine for amalgamating minerals and other metalliferous and metallurgical products or substances.

Dated March 26, 1863.

789. G. Cowdery, Llanmynech, Salop, civil engineer. Improvements in machinery for making bricks.

791. N. R. Hall, Rosherville, Northfleet, Kent. Improvements in construction of weighing apparatus.

793. T. Parkinson, salesman, and J. Wood, embroiderer, Manchester. An improved application of embroidery to cotton printed fabrics.

795. G. Davies, No. 1, Serle-street, Lincoln's-inn, civil engineer. Improvements in engraving upon metals. (A communication.)

797. J. Norton, Bray, Wicklow, Ireland, Esquire. Improvements in projectiles or ignition missiles.

799. F. Applegate, Bradford-on-Avon, Wilts, woollen manufacturer. Improvements in railway carriage doors.

Dated March 27, 1863.

801. J. Grantham, 31, Nicholas-lane, civil engineer. Improvements in apparatus connected with machinery used in manufacturing compressed fuel.

803. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in machinery for scouring wool. (A communication.)

Dated March 28, 1863.

809. A. H. Perry, Guildford-road, Brighton, railway inspector. Improvements in working railway points, switches, and signals, and in the apparatus to be employed for that purpose.

811. J. Leeming and R. S. Markindale, worsted spinners, Broughton, Lancaster. An improvement in carding engines.

813. W. Symons, Hatton-garden, philosophical instrument maker. Improvements in barometers.

815. J. Dale, Manchester, manufacturing chemist, and G. Bischof, jun., Swansea, Glamorgan, chemist. Improvements in the manufacture of aniline, napthylamine, and other analogous bodies, and in apparatus connected therewith, which apparatus is also applicable to obtaining finely divided metallic iron for other purposes.

Dated March 30, 1863.

819. H. Hughes, Homerton, Middlesex, engineer. Improvements in machinery for shaping metal and plastic substances.

821. W. E. Newton, 66, Chancery-lane, civil engineer. An improved process for producing yellow colouring matters, and other colours which may be derived therefrom. (A communication.)

823. J. Payne, Kircudbright, ironmonger. Improvements in fire-escapes.

Dated March 5, 1863.

825. J. Smethurst, Royton, Lancaster, coal proprietor and millowner. Improvements in steam engines and boilers, art of which improvements is applicable to heating purposes.

827. R. Furnival, Manchester, machine and tool maker. Improvements in and applicable to platting or braiding machines.

829. A. H. Bell, Dover, Lieutenant, R.A., and V. G. Bell, Woburn-place, civil engineer. An improved mode of constructing the armour of vessels of war.

831. E. O. Coe, Brook-street, Grosvenor-square. Improvements in propellers for ships and other vessels.

833. J. M. Dunlop, Manchester, engineer. Improvements in machinery for ginning cotton.

Dated April 1, 1863.

834. J. S. Grimshaw, Huncoat, near Accrington, Lancaster, spinner and manufacturer. Improvements in carding engines.

835. J. Hindle, Sabden, calico printer, W. F. Calvert, Enfield, cotton spinner, and E. Thornton, Padiham, manager. Improvements in looms for weaving.

837. J. Bray, Stretford, Lancaster, plumber, painter, and glazier. Improvements in the construction of omnibuses, railway carriages, and other vehicles.

838. M. Henry, 84, Fleet-street, patent agent. An improved method of lubricating. (A communication.)

840. W. West, Euston-road, civil engineer. Improvements in working railway signals.

841. W. Mitchell, Carlton-hill East, St. John's-wood, gentleman. An improved process for coating iron. (A communication.)

843. E. B. Wilson, 5, Parliament-street, Westminster, engineer. Improvements in the manufacture of iron and steel and other metals, and in the apparatus employed therein.

Dated April 2, 1863.

847. E. F. Clarke, Holmer-road, Widemarsh, Holmer, Hereford. Improvements in the means of fastening rails for railways.

849. J. Cassell, La Belle Sauvage-yard, publisher. Improvements in stills for the distillation of petroleum and other heavy oils.

851. W. Jones, Liverpool, boiler maker and iron shipbuilder. Improvements in the construction of ships or vessels, part of which improvements are also applicable for constructing buildings, and for various other purposes in which rolled iron is employed.

Dated April 4, 1863.

854. A. Stewart, Helensburgh, Dumbarton, saddler. Improvements in saddles.

856. J. Blain, Manchester, commercial traveller. Improvements in the finish of threads and yarns.

857. P. Hanrez, engineer, Marchiennes au Pont, Belgium. Improved machinery or apparatus for drying coal, grain, and other substances.

859. W. H. Perkin, Seymour-villa, Sudbury, Middlesex. Improvements in the manufacture of red and orange colouring matters.

861. J. Gimson, Leicester, engineer. Improvements in the means of actuating shuttles in looms for weaving narrow fabrics.

863. P. Spence, Newton-heath, near Manchester, manufacturing chemist. Improvements in the manufacture of sulphuric acid and sulphate of iron.

Dated April 6, 1863.

865. B. Cooper, Frome, Somerset, manufacturer. Improved apparatus for feeding scribbling or carding engines.

869. J. Railton, iron founder, and H. Booth, manager, Blackburn, Lancaster. Improvements in machinery for carding cotton and other fibrous substances.

Dated April 7, 1863.

873. H. Gilbee, No. 4, South-street, Finsbury. A new composition for dressing and preparing silk, cotton, and woollen tissues and fibres, and also mixtures of the same. (A communication.)

877. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in polishing precious and other hard stones, and in the machinery or apparatus employed therein. (A communication.)

879. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in reproducing or obtaining facsimiles of the veins, pores, knots, and figures of wood upon paper and other surfaces. (A communication.)

881. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improvements in projectiles for ordnance, and in fuses therefor. (A communication.)

Dated April 8, 1863.

883. W. Simpson, Liverpool, gentleman. Improvements in insulating the magnetic needle or needles in compasses.

885. J. N. Brown, Handsworth, Stafford, gentleman. Improvements in securing or connecting the bearing springs of railway carriages and waggons to the axle boxes of the said carriages and waggons.

886. T. Gray, Lower Mitcham, Surrey, bleacher. Improvements in preparing and bleaching jute and other vegetable fibres for spinning and other purposes.

887. J. R. Harris, Hawley-road, Kentish-town, house decorator. Improvements in propelling vessels.

889. W. H. Mitchell, Hampstead, gentleman. An improved construction of barometer.

891. A. Kinder, 20, Cannon-street, engineer. Improvements in coating or covering lead or alloys of lead with tin or alloys of tin, and in the apparatus employed therein.

Dated April 9, 1863.

893. D. J. Cooke, Manchester, dyer and finisher. Improved compounds or compositions for sizing, stiffening, and colouring yarns and textile fabrics.

894. T. T. Heath, Liverpool, artist. The application of glass for ceilings and the like overhead parts of houses and other structures.

897. A. Hett, London, Doctor of Medicine, and F. W. Basset, Camberwell. Improvements in preventing the fouling of ships' bottoms, and in cleansing the same when fouled.

899. R. K. Penson, Ferryside, Carmarthenshire. Improvements in apparatus used for warming railway carriages. (A communication.)

903. G. Low, Newark-on-Trent, Nottingham, engineer. Improved machinery for boring rocks and other hard substances.

Dated April 10, 1863.

905. G. Colomb, Aigle, Vaud, Switzerland, civil engineer. A process of manufacturing factitious blocks of wood of diversified shades and hues proper for veneering and other purposes.

907. T. Baldwin, Bury, Lancaster, engineer. Improvements in superheating steam, and in apparatus connected therewith.

909. H. R. Spicer, 3, Clement's-lane, Lombard-street, ship broker. Improvements in boxes or cases for the enclosure and preservation of human remains.

910. R. Smith, 10, Southampton-terrace, Crompton-road, Islington, gentleman. An improved medicated oil for the preservation of metal, wood, or stone.

911. J. Wightman and C. Dening, Chard, Somerset, agricultural implement makers. Improvements in horse rakes.

913. H. W. Ripley, Montpellier-lawn, Cheltenham. Improvements in machinery for preparing and printing wool and other fibres. (A communication.)

Dated April 11, 1863.

915. F. Versmann, 7, Bury-court, St. Mary Axe, consulting and analytical chemist. Improvements in moulding machines.

917. D. Mylrea, Church, near Accrington, Lancaster, millright and engineer. Improvements in fire-bars or furnace grids.

919. J. Farrar, Halifax, machine maker. Improvements in machinery or apparatus for twisting and doubling yarns of wool or other fibrous substances.

921. P. P. Baly, 4, Robert-street, Adelphi, civil engineer. Improvements in constructing breakwaters, piers, sea walls, and other similar structures.

923. C. A. Collins, Trowbridge, Wilts, gentleman. An improved method and apparatus for loading carts and waggons with hay, straw, and other similar products.

Dated April 13, 1863.

925. J. Gill, Mid Lothian, Edinburgh. Improvements in printing machinery.

927. R. Leggett, engineer, and R. Gittus, farmer, Mildenhall, Suffolk. Improvements in the construction of machinery or apparatus for cutting chaff and other agricultural produce.

928. J. Lark, White Lion-wharf, Bankside, Southwark. Improvements in the manufacture of artificial fuel and cement.

929. R. Reeves, Bratton, Wilts. Improvements in the manufacture of liquid manure drills.

931. M. Myers, Wigmore-street, Cavendish-square. Improvements in the construction of trunks, portmanteaus, and boxes.

Dated April 14, 1863.

933. J. Nasmyth, foreman, and S. Thornton, Manchester, mechanical draughtsman. Improvements in machinery for carding cotton and other fibrous substances.

935. G. T. Smith, Horsdall-house, East Retford, Nottingham. Improvements in metallic window shutters.

937. J. Combe, engineer, and J. H. Smalpage, woollen draper and tailor, Leeds. Improvements in the action and arrangement of machines for winding cops; in the construction and arrangement of banks for holding cops for warping purposes; in the formation of shuttles for receiving cops; and for apparatus for packing and securing cops in shuttles—one part of which improvements, consisting of a spring clutch, is applicable to machines in general.

939. H. Trapnell, Bristol, mahogany merchant. Improvements in vent pegs.

941. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in lamps for burning light and heavy mineral and vegetable oils. (A communication.)

Dated April 15, 1863.

943. J. Leach, Cheadle, Chester, commercial clerk. An improved machine or apparatus for washing, squeezing, mangling, and churning.

947. H. A. Bonneville, 24, Rue du Mont Thabor, Paris, patent agent. Improvements in the construction of gas burners. (A communication.)

949. W. Spence, 50, Chancery-lane, patent agent. Improvements in the manufacture of gunpowder. (A communication.)

951. J. S. Morton, Northampton, cabinet maker. Improvements in locks.

952. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. An improved construction of blowing apparatus. (A communication.)

953. T. B. E. Fletcher, Birmingham, doctor of medicine. Improvements in apparatus for collecting the solid portions of sewage.

Dated April 17, 1863.

964. S. Riley, Oldham, Lancashire, agent. Improvements in the manufacture or preparation of cocoa and chocolate.

Dated April 18, 1863.

972. C. W. Siemens, 3, Great George-street, Westminster, and F. Siemens, Birmingham. Improvements in furnaces which are principally applicable to the smelting of iron.

974. T. A. Weston, Birmingham, mechanical engineer. Improvements in ratchet levers.

976. G. A. Buchholz, Montague-place, Clapham-road, engineer. Improvements in apparatus for hulling grain, and for reducing granular substances.

Dated April 20, 1863.

980. G., W., and J. Graham, Burnley, Lancaster, machine makers. Improvements in machinery for folding, or plaiting fabrics.

982. J. Robey, Newcastle-under-Lyme. Improvements in apparatus for separating fluids from more solid matters mixed or combined therewith.

Dated April 21, 1863.

988. E. L. Simpson, Bridgeport, Fairfield. An improvement in waterproof compounds, and in fabrics prepared therewith.

990. M. Runkel, Centre-street, New York, engineer. Improvements in marine steam-engine governors. (A communication.)

994. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in wrenches. (A communication.)

996. W. Campion and G. Wilson, Market-place, near Sneinton, Nottingham, general mechanists. Improvements in machinery or apparatus employed in the manufacture of looped fabrics.

Dated April 22, 1863.

998. F. E. Byrant, Alfred-street, Bedford-square, gentleman. Improved apparatus for ascertaining the temperature of steam and its power of tension. (A communication.)

1000. F. Durand, Paris, mechanical engineer. Improvements in moulding articles of china or other clay or of other plastic materials.

Dated April 23, 1863.

1008. J. Whitley, J. B. Pope, and J. W. Burton, Leeds. Improvements in the manufacture of metals.

1010. W. E. Newton, 66, Chancery-lane, civil engineer. An improved mode of repairing worn-out files and rendering them again fit for use. (A communication.)

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated April 24, 1863.

1020. R. Lavender, 332, Goswell-road, Islington, ink manufacturer. A new compound to be used as a lubricator.

Dated April 28, 1863.

1065. G. W. Fuller, Cambridge-port, Middlesex. A new and useful or improved submarine lantern to be used in explorations beneath the surface of the ocean or any other large body of water.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, May 5, 1863.

3409. J. Platt and W. Richardson. Scutchers or beaters of cotton machinery.

3421. C. Pieper. Governor.

3424. C. A. F. Collette. Lace.

3429. S. Russell. Stereoscopes.

3434. F. N. Gisborne. Indicating the speed of ships at sea.

3444. J. Taylor. Carding.

3445. J. and W. Lord. Machinery for fluting rollers.

3454. E. T. Loseby. Ascertaining the pressure and moving force of the atmosphere.

3456. W. H. Samson. Cultivating land.

3459. J. Petrie. Valves for steam engines.

3460. M. Ker. Wardrobes or other pieces of furniture.

3461. J. G. Taylor. Dress fastenings.

3470. J. Johnston. Surface refrigerator.

3475. W. and H. Bowser. Coating or protecting iron or steel.

3481. R. Bottomley. Twisting and doubling.

3485. J. W. P. Field. Breech-loading firearms.

4. M. E. Bowra and A. E. Francis. Manufacture of elastic fabrics.

9. W. Soutter. Raising and planishing metals.

10. W. Robinson. Glasses for lamps used in ships and railway carriages.

26. S. White. Purifying, bleaching, and refining oils and oily and fatty matters.

27. W. Astrop. Manufacture of paper.

28. C. B. Clough. Curing smoky chimneys.

29. W. Tolson and C. Brown. Treating or covering strip steel or other suitable material for the making of crinoline and other similar purposes.

33. J. A. Cooper. Application of a fibre obtained from a certain plant as a substitute or to be used with silk, cotton, flax, and such like materials.

34. J. Howard and J. Bullough. Warping or beaming machines.

51. J. Whitworth and W. W. Hulse. Ordnance.

61. T. Aveling. Traction engines.

99. W. E. Newton. Application of power designed for stationary and traction engines, propellers, and other machinery. (A communication.)

117. J. A. Schlumberger. Manufacturing colours for dyeing and printing. (A communication.)

216. W. Mellor and W. Whaley. Steam hammers.

256. W. Clark. Copying and reproducing sculpture. (A communication.)

308. W. E. Newton. Reflectors. (A communication.)

320. C. and D. Faulkner, J. Fairley, and W. C. Stiff. Manufacture of gun barrels.

394. O. H. Hodge. Manufacture of hat brims.

485. W. H. Gauntlett. Manufacture of iron.

501. G. Davies. Melting and smelting furnaces. (A communication.)

622. W. Jackson and R. Watkins. Steam engines.

693. J. W. McCarter. Sawing or cutting wood.

719. W. Symington. Roasting and treating coffee and other organic substances.

861. J. Gimson. Actuating shuttles in looms for weaving narrow fabrics.

879. R. A. Brooman. Reproducing or obtaining facsimiles of the veins, pores, knots, and figures of wood upon paper and other surfaces. (A communication.)

899. R. K. Penson. Warming railway carriages. (A communication.)

906. S. A. Couperie. Semicircular metallic slide.

924. J. Ramsbottom. Machinery for hammering, rolling, and shaping metals.

962. F. A. E. G. De Massas. Peeling grain and seeds.

1020. R. Lavender. Lubricator.

1065. D. W. Fuller. Submarine lantern.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed May 1, 1863.

2806. W. S. Kennedy.
2987. A. C. Dewies.
2993. R. A. Brooman.
2994. R. A. Brooman.
2995. R. A. Brooman.
3006. H. Griffin.
3007. W. N. Hutchinson.
3066. E. S. Cathels.
3112. R. Hardman.
3220. W. Clark.

Sealed May 5, 1863.

1958. J. McGeary.
3015. H. Gardner.
3018. C. W. Spruyt.
3022. G. Kent and E. P. Griffiths.
3026. J. Whitaker.
3031. J. Shanks.
3035. G. F. Lyster.
3043. W. and J. Galloway.
3090. C. Littleboy.
3099. R. Brown.
3151. R. and W. Hawthorn.
3188. J. T. Caird.
3224. A. V. Newton.
3285. P. Todd.
3408. A. V. Newton.
3472. J. H. Johnson.
113. J. B. Rock.
447. F. J. Reed.
456. J. J. Badart.
618. W. Allen and W. Johnson.
631. J. Morris and T. Newton.
636. A. Wilson.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

1121. D. West.
1198. J. Denis.
1085. G. Masure.
1138. W. Evans.
1178. J. Chatterton and W. Smith.
1095. F. Preston.
1108. J. Gardner.
1111. J. Brickhill and J. Noble.
1119. T. Heatley and W. Paddock.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

1095. F. Potts and T. Vann.
1033. R. A. Brooman.
1058. I. Holden.

MECHANICS' MAGAZINE.

LONDON, FRIDAY, MAY 15, 1863.

OSCILLATION OF LOCOMOTIVES.

FEW subjects connected with the locomotive have met with more attention than its oscillation at high speeds. Careful experiments have been conducted, long treatises written, and discussions seemingly endless carried on, to ascertain its cause, its amount, and its remedy. In the infancy of the locomotive, regarded as a matter of little importance, we find it of late looked on as a matter of increasing moment, concerning not alone the stability of the permanent way, the wear and tear of the engine, and the economy of fuel, but even the lives and limbs of passengers: many of our most deplorable railway accidents being doubtless the result of an oscillation so excessive as to force out a rail, or break a leading wheel-flange. Nevertheless, all that has been hitherto said, written, or done, has not only failed to give us a steady engine, but even to give a satisfactory answer to the question, "What causes oscillation?" At the present moment three parties may be found, each representing our highest talent and scientific skill—one holding that its sole cause must be found in the want of balance in the reciprocating masses of the engine; another, that it is wholly due to imperfections in the permanent way; and the third, and by far the most numerous, that it is the result of both these disturbing causes. Although the opinions of the last party are doubtless correct as far as they go, still they are faulty in that they almost totally disregard one or two disturbing forces of considerable but much underated importance, to which we wish to call the attention of our readers.

Mr. D. K. Clarke conducted a very valuable series of experiments some years ago—we forget the exact date,—to determine the effect of want of balance in the reciprocating machinery of a locomotive. In order to obtain accurate results, he suspended the engine by long ropes from the roof of the workshop, and fixed a pencil to the front or back buffer beam in such a manner that the oscillation, when the driving wheels were put in motion, was registered on a cord suitably placed. The resulting diagram, with an unbalanced engine, was just ⅛ of an inch long, oval in shape, and about ½ inch wide. Weights were then applied on the trial and error system, and the result was, that the oscillation decreased by degrees, as proper weights were better distributed, until the diagram from a perfectly balanced engine dwindled down to a mere point. Such a locomotive was found to run much steadier in regular work than before it was balanced, although a ride on the foot-plate demonstrated plainly enough that it was still far indeed from being perfectly steady; better it certainly was, so much better, indeed, that it became practicable to run at speeds which it would have been madness to attempt had it not been balanced. The remaining oscillation was attributed naturally enough to imperfections in the permanent way; much of it is due to this cause, no doubt, but not all.

There are some points worthy of note in these experiments—one, that the pressure in the cylinders never exceeded the few pounds on the square inch necessary to overcome the friction of the engine, the driving wheels resting neither on the rails or a brake; another, that there was no propelling thrust whatever on the axle boxes. The experiments were perfect, and attended with the happiest results, as far as they dealt with want of balance as a cause of oscillation; but dealing as they did with an engine under abnormal circumstances, they were utterly useless as far as any other disturbing causes were concerned. They could give us no idea of the effects produced by the drag of a loaded tram, itself oscillating violently, the imperfect state of the permanent way, the want of truth in the diameters of the wheels, or many other things—trifles, it is true, by themselves, but of considerable influence when taken in the aggregate.

As unsteadiness remains after the most accurate balancing, it is quite evident that some other disturbing cause is at work; that this is not wholly due to imperfect rails, is proved by a fact well-known to most drivers, namely, that the character of the oscillation changes in any engine the moment steam is shut off, although the speed is still the same. This, it is true, may not be always evident, for the permanent way may be so uneven as to become a disturbing force, so great as to swallow up, as it were, all other causes of oscillation; but the statement is so correct, in a general way, that it might be worth while to undertake a series of experiments, which would determine exactly the character of the oscillations when the engine was, and was not, under steam at a high speed on a good and level road. We have little doubt that such experiments might afford very valuable results. We should always avail ourselves of every scrap of information, which can throw light on a doubtful subject.

Admitting, as we do in the fullest degree, that want of balance, and faulty permanent way, are two principal sources of oscillation, there remains, as we have already said, a third, which has not as yet received anything like the attention it deserves; it is simply that the centres of propulsion are constantly changing while the engine is in motion.

Most writers on this subject take it for granted that the locomotive is propelled solely by the forward thrust of the axle, or crank shaft, in its brasses—a strange error, for not only is it propelled by this thrust, but also by the direct pressure on the forward cylinder covers; and this not indirectly, but directly; and instead of the crank shaft always pressing forwards, as does the shaft of a steamer with vertical cylinders, it presses both backwards and forwards with nearly equal force, once each way in each revolution. When the piston is moving forwards, the pressure on the back cylinder lid is precisely equal to that on the piston, and of course no locomotion could be produced, were it not that the piston acts through the medium of the connecting rod and crank pin, then above the wheel centre, with a leverage equivalent to the distance of the crank pin above the rail, as compared with the distance of the wheel centre from the same. If we suppose, for the sake of illustration, that the wheel is 4 ft. in diameter, and the stroke 2 ft., it is evident that when the crank is vertical, the strain on the axle brass will be just one-third more than that on the cylinder lid; and the engine will, in consequence, advance on the rails against the retarding force due to that pressure, solely by the action of the crank shaft; but when half a revolution is completed, we find that the crank pin is now vertically below the wheel centre, and as the radius of the wheel is 2 ft., and the length of the crank 1 ft., it is evident that, so far from the crank shaft propelling the engine, it now retards it with a force just half that of the whole pressure on the piston—in consequence, the engine is wholly propelled by the pressure on the forward cylinder cover, the piston being held in space as regards the forward motion of the engine on the rails, and acting as the fulcrum for the steam in the cylinder. The pressure is thus transferred from the axle-box, which gives its thrust in a line with the frame to a point inside or outside it, according to the arrangement of the cylinders, twice in each revolution—a fact, in itself, sufficient to account for a very considerable oscillation, independently of the change of position of the centre of propulsion from a part of the engine close to the centre of gravity to one far in advance of it. If we draw a railway waggon, by a rapid succession of pulls, first at one of the front corners, then at the other, it would be folly to assert, that oscillation would not necessarily ensue, yet each cylinder lid does this many times in a second with a locomotive running at high speed.

It has been urged, however, that the wheels being keyed on a shaft strong enough to prevent sensible torsion, the thrust forwards must be the same in both axle-boxes—an assumption contrary to fact, for the forward thrust in one box, even if we supposed one cramp to be straight up while the other is straight down (which, of course, never occurs in practice), would be, in the case we have supposed, one-third more than the whole pressure on the one piston, while the tendency of the opposite piston to force the other end of the shaft against the back brass is equal to half the whole pressure on its surface. When we consider that, in actual practice, one crank is always at the dead point, while the other is exerting full power, it is easy to see that the action of the pistons must constantly tend to twist the driving shaft out of right angles with the rails by as great a distance as the play of the axle-boxes in the horn-plate will permit. It is impossible to make these boxes fit the horn, plate slides at first with mathematical accuracy, and, of course, after the engine has been a few months at work, they will get much worse; we do not think we exaggerate, when we say that, the play here may amount, on an average, to as much as one-eighth of an inch for each box. It is evident, therefore, that each side of the engine may be thrown backwards and forwards alternately, through a distance equal to this play, provided the wheels do not slip on the rails. One-eighth of an inch of longitudinal oscillation at the axle-boxes, may amount to more than half-an-inch of transverse oscillation at the forward end of the engine—an amount equal to that produced by want of balance, as demonstrated by Mr. Clarke.

If, however, the inertia of the mass of the engine is greater than the adhesion of the wheels, they may slip a little in advance of each other alternately; and the axle, no longer at right angles to the rails, will of course tend powerfully to throw the leading flanges against them, when the recoil of the wheel from the elastic rail may be quite sufficient to set up a long-continued and dangerous oscillation.

We have hitherto spoken very much as though our suppositious engine had but one cylinder; but the question assumes a very complicated form, when we consider the varying action of two pistons. We shall then find that the engine is first driven forward by the pressure of the steam on, say the left-hand cylinder lid; then by the pressure on the same lid and the right-hand axle-box; then by the strain on this box alone; then by the strain on both boxes; then by the strain on the right-hand cylinder cover, and so on; the consequence being that all these forces varying constantly, both in direction and amount, give resultants constantly changing, and seldom or never passing through the centre line of the engine. We know the result.

While considerable oscillation exists we can never have a really permanent way. It is too much the habit to attribute the derailment of a locomotive to a faulty rail. Oscillation may easily become so excessive that either rails and chairs give way, or the engine mounts the trucks. We acknowledge the difficulty of pointing out a remedy. At low speeds the oscillation is seldom so great as to be regarded as of much consequence; at 50 or 60 miles per hour it becomes a plentiful source of accident. Engines are so accurately balanced in modern practice, that we have nothing to hope from any further development of that principle. The single cylinder arrangement seems, with many drawbacks, to hold out much that is desirable; the resultant of all the forces due to the action of the steam must be central, and we believe such an engine, carefully balanced, would run almost free from oscillation, other than that due to the faults of the permanent way; the objections raised against it, of difficulty in starting trains, and the increased height of the centre of gravity, although of some weight, are far from insuperable. Many expedients might be employed to obviate the first difficulty, which would be of less importance, as this arrangement would, of course, only be applied to fast express engines, which would run 80 or 90 miles without a stop. A pilot engine could easily be provided to start them from a station, as is very frequently done now, when an express engine has a heavy train to deal with.

The second objection is of little weight. Mr. Clarke proves conclusively enough that a high centre of gravity affects the stability of an engine very little indeed, and even that need not be raised if we adopt a 7 ft. wheel, which is large enough for the highest speeds, instead of the 7 ft. 6 in. and 8 ft. wheels now frequently met with.

WROUHT-IRON BOILER TUBES.

It is well known that brass boiler tubes are generally adopted in England in preference to those of iron; nevertheless, some railway companies use iron tubes to a great extent. A difference of opinion still exists as to the comparative advantages of the two kinds; a series of experiments and a record of actual results are the only means to get at the truth of such matters. For some time the Prussian Government railways have been using wrought-iron boiler tubes for their locomotive engines. Results extending over several years allow us to believe that this kind of tubing is at least equal in strength and duration to brass tubes; while for locomotives, iron tubes are superior in economy with regard to first cost, repairs, and renewal. It is generally found that they are less subject to split in the direction fo their axes, and thus cause leakages, than brass tubes. No case has yet occurred of the explosion of one of these pipes; an accident which is not unfrequent with brass tubes. Wrought-iron tubing can also be fixed without the inside ferrules that always somewhat diminish the useful heating surface. Being of the same metal as most of the other parts of the boiler, they are subject to a similar amount of expansion and contraction by heat, and the different parts are thus better united together. The objections that have been raised against wrought-iron tubes consist in their favouring the increase of incrustation in the boiler, in being fixed with greater difficulty to the tube plates, and in forming leaky joints. With regard to the last objection, that of liability to leakages at the joints, it may be stated that this fault does not seem to be inherent to iron tubes; at least when the fire-box and smoke-box tube-plates are new, the holes are exactly drilled, and the caulking is properly done. Wrought-iron tubes, when first introduced, were naturally employed to replace those of copper or brass, and thus the holes in which they were to be fixed lost their circular shape and regularity in consequence of repairs and previous working. Copper and brass tubes, possessing more malleability, suited themselves to any irregularities, and could form tight joints, being in this respect superior to iron tubing. Generally speaking, it is to be remarked that iron tubes often require to be replaced when the fire-box and smoke-box tube-plates are in a bad state; the most frequent cause being leakages at the joints; and when iron tubes once become leaky, their ends get soon wasted away, and cannot afterwards be depended upon. The *Zeitschrift für Bauwesen* gives the following comparative results as to the use of this description of tubing. The engine No. 23, on the Aix-la-Chapelle to Dusseldorf line, was fitted with iron tubes since the year 1857; and, up to the latter end of the year 1861, the engine had run 78,747 kilometers without any accident to her tubes. On several other German lines iron tubes have been used almost exclusively since 1857-58.

Iron tubing has been used on the Westphalian net of lines since 1857. During that year six engines were made with iron tubes; and in order to institute an exact comparison as to the relative advantages of the two kinds of tubing; a few months later, six other engines were made with copper tubes. By the month of October, 1861, 214 of the 978 tubes (21·9 per cent.) contained in the first six engines had been changed. The tubes had been on an average 28 months in use, and had run 69,500 kilometres. The six locomotives, taken together, had travelled in all 295,380 kilometres, but one of the six had travelled 98,000 kilometres, which accounts for the average run of the tubing being nearly 70,000 kilometres, while the average distance run by the engines experimented with is only 50,000 kilometres. It may be taken for granted that the last engine could have run a further distance of 50,000 kilometres without using up her tubes.

In the six engines built with copper tubing there were 937 tubes; by the end of the year, 1861, 348 of these tubes had to be changed, (or 37 per cent.) after an average duration equal to 23 months, and an average run of 48,480 kilometres. The total mileage of the locomotives with copper tubing amounts to 344,415 kilometres, while that of the engine the most used equals 103,670 kilometres; and it was then calculated that the tubing would last for a further distance of 50,000 kilometres. If the iron tubes, instead of having only run 295,000 kilometres, had run 345,000 kilometres, like the brass tubes, the proportion of 21·9 per cent. of their renewal would have been raised

$$\text{to}\,\frac{345 \times 21{\cdot}9}{295} = 25{\cdot}6\,;$$

that is to say, 25·6 per cent. of the iron tubing would have to be replaced. This must be compared with the average of 37·1 per cent. given by the brass tubing. The Prussian line on which iron tubes are the most extensively employed, is the Niederschlesisch Markisch Railway; 30 locomotives are used for the traffic on that line, and are furnished with a total number of 4,503 iron tubes. Only 1·31 percent. of these tubes required changing in 1860.

According to Depretz, the conducting powers of iron and copper are respectively as the numbers 374 and 898, gold being taken at 1,000. These powers, however, are subject to great variation under the influence of practical conditions. The numbers cited above have been obtained when the surfaces of the metals were clean and bright, and were not subject to those practical influences that often completely modify the expectations formed by calculation. In the year 1857, Mr. Tosh, of Maryport, read before the Institution of Mechanical Engineers a short account of some experiments he had carried out in order to ascertain the relative conducting powers of brass and iron tubes. He used two vertical boilers of equal dimensions, 6 in. diameter and 2 ft. long, with a single tube in the middle of each 2 in. external diameter and No. 14 wire gauze thickness, of brass and iron respectively. "The two boilers were filled with water of the same quality and of the same temperature, and alternately placed upon a stand in the same position over a gas flame; they were each exposed to the action of the gas for the same length of time, which was equivalent to the same quantity of fuel being consumed in each case; and the height of water was carefully gauged after each experiment as soon as ebullition had ceased." Great care was taken to prevent any change in the pressure of the gas. According to Mr. Tosh's experiments, the evaporating power of brass is to that of iron as 125 to 100; or brass will evaporate about 25 per cent. more water than iron, with the same quantity of fuel. Experiments were also made with brass and copper tubes, and copper was found to be as superior to brass as brass to iron. The relative evaporating powers of copper and iron were found to be as 156 to 100, and, according to this result, copper should evaporate 56 per cent. more water than iron, using an equal amount of fuel. In the discussion that ensued, Mr. Tosh said that the consumption of gas had not been regulated by a meter, but a uniform pressure had been attained by applying to the authorities of the gas works.

Professor Rankine said that a number of experiments had been tried many years ago with experimental boilers of iron and copper of different thicknesses. These experiments were tried by Mr. James R. Napier, and he heated the boilers over the same gas flame, but found only a slight difference in *evaporating* power of about 1-20th or 1-30th to the advantage of the copper. Professor Rankine stated that in all experiments of the kind the state of the heating surface was an important matter; as to whether it was smooth or rough, either perfectly clean or encrusted to any great extent. The effective evaporating result, or transmission of heat through metal, as was also stated by Mr. Rankine, evidently depends on three properties:—"1st, the resistance of the first surface to absorption of heat from the heated air and gases; 2nd, the resistance of the internal particles of the metal to the conduction of heat; and 3rd, the resistance of the second surface to giving off heat to the water:—those three properties were not possessed in the same proportion by different bodies; the resistance to internal conduction was less in copper than in iron, but the resistance of the surface was greater in copper." Mr. Rankine recalled to the minds of the members of the Institution the well-known experiments on the transmission of heat, made by Mons. Peclet, who found that metals all conducted pretty much the same when their surfaces were dull. It is evident that, in the experiments we have cited, the tubing was scarcely under the same practical conditions as in a locomotive boiler. Mr. Siemens alluded to another difference, owing to any variation of the draught on the gas flame through either of the tubes carrying off the heat with greater speed; "the brass tubes might also gain an advantage from their smoother surface causing less adhesion of the minute bubbles of steam during slow ebullition, though that circumstance would not apply in rapid ebullition." It would thus appear that iron tubes are practically equal in heat transmitting powers to brass tubes. As regards duration, they actually appear to be superior to brass tubes, especially when any leakages are avoided by careful attention and workmanship. II.

WEIGHTS OF EXPERIMENTAL TARGETS.

One of the objects of the target trials at Shoeburyness is to ascertain what description of armour-plating is best adapted for the protection of our iron-clads. Two points have to be considered—invulnerability and weight. One must not be sacrificed to the other. They are inseparable. The problem is the combination of the two in the most efficient manner. Invulnerability might be attained by unlimited increase of weight. But the very nature of a ship, as a floating body, fixes a limit of weight which cannot be exceeded. This essential condition seems to be lost sight of by some inventors.

The standard of the weight of armour for a line-of-battle ship, adopted by the Admiralty, is the weight which a frigate of the "Warrior" class immerged to the load line, after allowing for the weight of the ship with her engines, armament, fuel, and stores on board, can carry consistently with her efficiency as a fast sea-going vessel.

The following table, giving the weights of targets fired at, will be found useful in estimating their relative value in practice. The Admiralty very properly attaches the utmost importance to weight, in the construction of targets, of which it sanctions the trial at the public expense.

The plan on which the table is constructed, is to regard all the materials outside the frames of the ship, including the ship's skin, as constituting the defensive armour. The frames, deck beams, and shelf pieces belong to the ship; they differ somewhat in arrangement and dimensions; they constitute the back support to the armour, as well as the structure to which the armour is attached, but they are not the armour itself. To prevent, however, any erroneous impression, it may be as well to mention that the frames of the "Warrior" and "Minotaur" weigh less than those of any other of the targets. It will be seen that the armour of the Scott Russell, Chalmers, Inglis, and Brown targets exceeds the "Warrior" standard. With regard to the two last, as they are not planned for ships' armour, the excess is only to be considered in comparing their resisting force with other targets. But the Scott Russell and Chalmers' systems being expressly designed for ships, their great excess of weight must be taken into account, in estimating their value for the public service.

The following are the weights of the armour outside the ships' frames, including the skin plates, the frames being regarded as back supports:—

	lb. p. sq. ft.
Warrior:—	
Armour plate 4½ in. thick X 40 lb. p. ft. =	180
Teak backing 18 in. = 1·5 X 48 lb. =	72
Skin plates ⅝ in thick =	25
	277
Minotaur:—	
Armour plate 5½ in. thick X 40 lb. =	220
Teak backing 9 in. X 48 lb =	36
Skin plates ⅝ in. thick =	25
	281
Samuda:—	
Armour plate 5 in. thick X 40 lb =	200
Skin plate 1 in. thick X 40 lb =	40
Plate frames 2½ in. thick = ¾ all over =	30
	270
Iron Plate Committee:—	
Armour plate 5 in. thick X 40 lb =	200
Skin plate 1 in. thick X 40 lb =	40
	240

(A considerable part of the weight of the armour to the "Warrior" was incorporated in the structure of the frame of the Committee target by increasing the strength of the frames and fixing backing plates between them.)

Scott Russell:—	
Armour plate 5 in. thick X 40 lb =	200
Backing plates 2½ in. thick X 40 lb =	100
Skin plates ¾ in. thick X 40 lb =	30
	330
Capt. Inglis:—	
Armour plates of three degs. of thickness:	
8 in. X 5 in. = 13 in. X 40 lb. =	520
7 in. X 5 in. = 12 in. X 40 lb. =	480
6 in. X 5 in. = 11 in. X 40 lb. =	440
To each of these weights is to be added the weight of the supporting bars =	40
J. Brown & Co.:—	
Armour plates 7½ in. thick X 40 lb =	300
Teak 9 in. thick, at 48 lb. per cubic ft =	36
Skin plates the same as Samuda's =	70
The heaviest part of the target...	406
Armour plates 5½ in. thick X 40 lb =	220
Teak and skin plate as above =	106
The lightest part of the target...	326

Chalmers:—		
Outer armour plates 3¾ in. thick X 40 lb. =		150
Inner armour plates 1¼ in. thick X 40 lb. =		50
Teak 15 in. thick	15	
Less 10 per cent. for thickness of the ⅜ in. iron plates	1·5	
	In. 13·5	
13·5 in. = 1·125 cubic ft. at 48 lb =		54
⅜ in. plates, 11 in. wide and 5 in. apart equal to 1 in. all over =		40
Vertical 1⅜ in. tie rods and bolt-head washer blocks let into the backing, equal per foot to		20
Skin plate ⅝ in =		25
		339

The weights of the Scott Russell and Chalmers' targets, respectively, are 53 lb. and 62 lb. in excess of the "Warrior," making a difference equal to 1·325 and 1·5 in. of iron in the thickness all over, and of 200 to 250 tons additional weight to be carried by a ship of the "Warrior" class.

HEAP'S SCREW STOCKS AND DIES.

A patent has been obtained by Mr. J. Heap, of Ashton-under-Lyne, for an improvement in screw stocks and dies. This invention consists in making screw stocks of one piece, having dies, one or both furnished with a tail screw, on which is a nut fitting in a concave recess in the screw stock as hereinafter described.

The dies are portions of cylinders or of other suitable shape, and have V-grooves fitting on similar projections in the screw stock, which is made in the form of a fish belly at the centre to combine strength with lightness and to reduce labour in constructing. The centre portion of the slot in the screw stock is enlarged to allow the dies to be put in their places and removed.

The dies may be made of cylindrical pieces of steel, which are screwed into the screw stock. Each die may be provided with three cutting recesses for screwing bolts or other articles of different diameters. Fig. 1 is a side view, fig. 2 a plan, and fig. 3 a transverse section, of a pair of screw stocks and dies. The handles or levers *a*, *a*, of the screw stocks are forged or otherwise made of the same piece as the centre portion *b*, which is made, above and below, in the form of a fish belly, as shown in fig. 3, in order to combine strength with lightness, and to reduce labour in the construction. The exterior edge of the centre portion *b* is turned in the lathe like the handles *a*, and the fish-bellied part may be either filed or ground. The dies *c*, *c*, are shown in the form of portions of a cylinder, but any other suitable shape may be given to them; the dies are made with tail screws *d*, *d*, having nuts *e*, *e*, which are convex at one side, fitting into concave recesses in the screw stock. The edges of the nuts are milled; and when the dies have to be brought closer together or set up, the workman turns the nut or nuts round or partly round. The sides of the dies *c* are made with V-shaped grooves, see fig. 3, which grooves fit on similar projections in the screw stocks; but these projections are cut away between the dies, as shown in fig. 2, to allow the dies to be put into their places or removed therefrom when required. In fig. 2 the dies are shown in their proper relative positions for screwing a bolt or other article; as soon as the screw has been cut, the attendant, by acting on the milled edge of one of the nuts *e*, liberates the dies from the screw. In changing the dies the attendant, by acting on one of the nuts *e*, draws one of the dies back until the end of the die comes against the nut; the other die is then drawn forward until the cylindrical portion comes opposite the space cut away in the centre of the screw stock; this die is then at liberty to drop out, and the other is removed in the same manner. In putting a fresh pair of dies into the screw stock, the same precaution is to be taken, that is to say, one of the screw nuts *e* is brought close up to the cylindrical portion of the die, which is then slipped into the screw stock, after which the other die follows, and then the dies are adjusted to the screws to be cut.

FIG. 1.

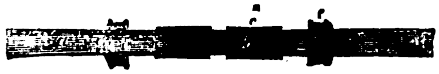

FIG. 2.

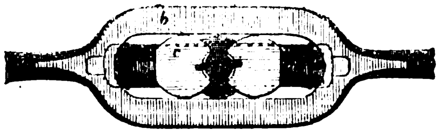

FIG. 3.

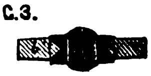

FIG. 4.

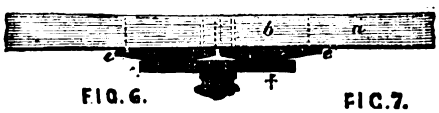

FIG. 6.

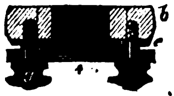

FIG. 7.

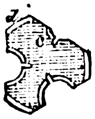

FIG. 5.

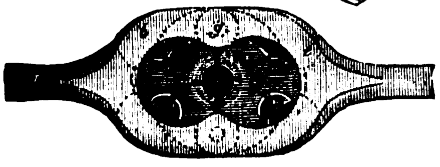

Fig. 4 is a side view, fig. 5 a plan, and fig. 6 a transverse section, of another form of screw stocks and dies. In this case the handles *a*, *a*, and centre portion *b* are of one piece, and the dies *c c*, are cylindrical pieces of steel, with three faces, fitting into similar spaces in the centre portion *b*; the dies have small shoulders *d*, seen best in fig. 7, to prevent them passing through the screw stock; they are retained in their places by the washer *f*, which is held up against the dies by the screws *g*, *g*. The dies are prevented from turning round by the plates *e* fixed to the under side of the screw stock. Each die is provided with three cutting recesses for screwing bolts or other articles of different diameters. The dies are made with three sides or faces, as the triangular form combines strength with the requisite variety in the diameter of the screws to be cut.

On referring to fig. 3, it will be seen that the groove in the dies is made diagonal instead of vertical as heretofore; the object of this is to increase the cutting action of the dies.

ON THE EDUCATION OF NAVAL ARCHITECTS IN ENGLAND AND FRANCE.*

In the buildings connected with our great naval dockyard and arsenal, at Portsmouth, there may be seen, said the author, a somewhat considerable building erected fifty years ago at a cost of £35,000. This large building is the dwelling-place of two modest officials, a clerk and an accountant, and from their tenancy the Admiralty derives a revenue in the shape of rental of £60 a-year. This building truly typifies and represents the condition of the science of naval architecture as it exists and is promoted by the Government of great naval England, and it truly represents also the provision which our nation makes for the continual supply, generation after generation, for the education of a race of naval architects worthy of the English Navy. The building in question is the Royal College of Naval Architecture. It represents truly naval science turned out of doors by the British Admiralty. It represents the naval architects of the nation expelled from their only seat of professional education, and their only source of scientific knowledge. It represents their vacant place taken by red tape, routine, and pennywise economy. It is the monument of a mutilated profession holding up in sight of the British public the stump of its right arm. There is another monument of a similar nature, less obvious, but nearer where we stand. There used to be part of a large building in London to which we could take the foreign naval architect and point out to him the last refuge of our destitute profession. There we could show him, if not principles of science, at least precedents of practice. There was a model room, almost a museum, in Somerset House, paltry indeed in comparison with those of any other country, but one in which we could point out and explain to him the peculiarities of the structures which had given to the fleets of England their known peculiarities; but this collection of precedents which embodied the principles of practical science is now also a type of the condition to which naval science has been reduced under our present Admiralty. It has been cast out of its fair rooms, it has been thrust down into a cellar, shut up in the dark, and is now effectually kept out of sight. Thus, in England, we have at the present moment professional science and education expelled from the Navy, and professional precedents and principles locked up in a cellar of Somerset House. The author next asked the audience to follow him on a little excursion across the Channel. Times, he said, have been a good deal changed of late in one respect. Naval architects, surveyors of the navy, ministers of marine, great admirals, and great naval commanders, used to come to Portsmouth, and Plymouth, and Chatham, and Woolwich, to search out and inform themselves in all that was most admirable in the design, construction, armament, and equipment of ships of war; for some few years that has ceased, and men have gone to Toulon, and L'Orient, and Paris, to see the progress and construction of the most famous and most powerful modern fleets of war, and there you now meet men of all nations assembled for that purpose. A friend conducted the author to a handsome palace in an agreeable quarter in Paris. They entered a large courtyard surrounded on three sides by a range of roomy and comfortable, though not costly buildings. It was the School of Naval Architecture. He entered and found installed in this school, and at the head of it, the eminent M. Reesch, one of the most eminent of naval architects, a good mathematician, an eminent man of science; he had occupied a distinguished position in one of the dockyard colleges, and not long ago had been transferred to Paris, where this central college of naval architecture had been established as a central point for pupils from all the dockyards of France. In this building were found all the means of an admirable education conveniently but economically provided: first, there were excellent lecture-rooms for the professors; second, there were study-rooms for the pupils; then large rooms with excellent drawing tables, one for each student, where, under the eye of competent naval architects and engineers, they make drawings, perform calculations, and produce designs; fourth, there was an excellent library, a large collection of drawings of precedents, and above all there was rapidly being formed and filled a model-room of naval structures of every kind. To show the result of this school, and the manner in which its pupils were appreciated in France, the author had only to say that so great was the demand for these trained naval architects, and so highly were they valued, that they could hardly be permitted to complete their third year of instruction. The pupils were not merely in the dockyards, but were to be found managing the largest and most prosperous engineering and shipbuilding establishments of France. The history of the School of Naval Architecture in England was soon told. It was established in 1810, because it was found by the inquiries of a special commission, that although the sailors of England were better than the sailors of any other country, the ships of England were in every respect their inferiors. Established in 1810, it was abolished by Sir James Graham, in 1833, because its pupils advocated the cause of science and professional skill as opposed to the empiricism which, at that moment, took possession of professional power in the navy—an empiricism which pretended to despise the laws of method and the principles of science, and soon met the usual fate of being trampled out by them in turn and extinguished. For more than twenty years this school sent out men fully armed with all the science of their day; but so far was the Admiralty from desiring their services, that, although forced by the country to educate them, they refused to employ them, they were denied promotion and even occupation; it was not till 1842, that they were permitted to exercise their vocation of even suggesting, advising, and making designs for new ships. Messrs. Creuse, Chatfield, and Reed prepared their designs of three classes of ships, and prepared also a report which was, in many respects, a model of systematic naval architecture as it existed at that date; their report did honour to the school which bred them; it showed what scientific education could do, because, although it was their first attempt, and although they had not been allowed to acquire any previous experience, by designing ships that were actually built, their vessels obtained with certainty and precision every condition for which they were designed; and although it had been objected that these vessels were deficient in the one quality of high speed, yet it must be remembered that no principle had gained general assent, or could be considered as fully established in their time, by which the quality of speed could be obtained with certainty, and without the sacrifice of any other good quality. The despised pupils of this school were afterwards found to be the only capable people at a critical moment when the whole navy of England had to be transformed from a sailing fleet into a steam fleet. It was most fortunate that England was able suddenly to lay its hands on a class of men of good education and matured minds in whose hands the transformation was speedily, effectually, and creditably accomplished. No sooner did the School of Naval Architecture rise into power, than they commenced the agitation of the educational question, and at the same time that they commenced the designs of their ships, something was done though only on a very small scale proportioned to their limited power for the advancement of professional education. And in 1844, there was founded once more in Portsmouth, a central mathematical school, called the School of Mathematics and Naval Construction. . . . He concluded by begging them to undertake the task of founding an English College of Naval Architecture, believing it perfectly practicable to carry it through, not without difficulty, but with complete success. There were among themselves in that room a sufficient number of able men to set going such an undertaking. The Council possessed all the skill to manage its organization, and direct its affairs. The power and weight of the society, augmented by its rapid success, and established usefulness, would give it a weight with the Government, and with the public, which it would be very difficult to resist. In such an Institution, the naval architects and shipbuilders of the private dockyards, would share equally in the advantages of high professional education; and he did not think it would be found to be without advantage that naval officers and engineers afloat should join in the completion of their studies in such an establishment; for he assured the members of the naval service present, that he knew it to be the opinion of naval officers, whose opinions were entitled to the highest weight—officers of other naval services as well as our own—that the next naval war would require of these officers, in addition to the highest skill in navigation, seamanship, and gunnery, a knowledge of the scientific properties of their ship, an acquaintance with the structure of the marine engine, a familiarity with the machinery which must steer their ships, as well as propel them, and with the mechanism which must work and divert their huge artillery, that would task the skill and science of officers infinitely more than their past service had ever done; and this he impressed on them the more now, because we stood at a transition point, where tradition, and routine, and experience of the past had become obsolete and inapplicable, and the man of the future was the man who has been acquiring unbounded knowledge, resources, and skill, and who was ready to bring them all to bear upon unforeseen circumstances and unprecedented combinations. All these wants then of every branch of the profession, the new Naval College might advantageously fulfil. What sort of course that education ought to be in detail, he would leave to the Council to consider and mature.

RECENT AMERICAN INVENTIONS.

At a recent meeting of the Franklin Institute, Philadelphia, Mr. Howson exhibited diagrams and models of A. B. Cooley's apparatus for obstructing rivers, consisting of a series of blocks or frames chained together, and anchored at each end of the series to one of the sides or shores of the river. Each block resembles a tetrahedron in shape (the points being tipped with iron or steel), so that upon whatever side the block may lie, a sharp apex will be presented, which should be about 5 ft. below the surface of the stream. The blocks are at such a distance apart that no war vessel of formidable size can pass through the channel without coming in contact with one or other of the frames. When no longer required to obstruct the channel, the blocks may be disconnected and separately removed.

Mr. Howson also exhibited several breech-loading firearms. The first is the invention of L. H. Gibbs, and manufactured by W. F. Brooks, of New York. In this arm the trigger guard is used as a lever, on depressing which the barrel is thrown forward, and tilted up at the rear, so as to expose the breech ready to receive a load. Another arm, the invention of B. F. Joslyn, of Connecticut, is closed at the breech by a cap hinged to the side and rear of the barrel, and is so constructed as to automatically discharge the empty cartridge case from the gun, on unclosing the breech.

---

* Read before the Institute of Naval Architects by Mr. J. Scott Russell, F.R.S., March 28, 1863.

H. Liebert's substitute for gunpowder was exhibited. Its principal ingredients are prussiate of potash and cyanide or ferro-cyanide of potassium. A powder composed of these two substances, in combination with nitrate of soda, charcoal, sulphur, and other ingredients, any or all of which may be employed, can be compounded without that danger of explosion which is incurred in making the ordinary substitutes for gunpowder, in which chlorate of potash is generally used.

Mr. J. N. Pierce, of Darby, Delaware Co., Pa., exhibited numerous specimens of artificial slate, for the use of schools, colleges, &c. On painting any suitable surface with a preparation, patented by Mr. Pierce, a slate-coloured ground will be formed which answers equally as well as slate for drafting or marking purposes. Paper, linen, or ony textile fabric may be used to form convenient portable slates, which can be rolled or folded up for transportation. Mr. Pierce also exhibited pencils made of talc.

INSTITUTION OF MECHANICAL ENGINEERS.

The general meeting of the members of this Institution was held on Thursday, the 7th inst., in the Lecture Theatre of the Midland Institute, Birmingham; Sampson Lloyd, Esq., in the chair.

The Secretary (Mr. W. P. Marshall) read the minutes of the last meeting, and several new members were elected.

The first Paper read was "On the Construction of Drawing Rollers, &c., for Spinning Machinery," by Mr. William Weild, of Manchester. After a reference to the early applications of machinery for spinning cotton fibre into thread, the present method of spinning was described, in which the sliver or bundle of cotton fibre is passed through a succession of grooved or fluted rollers, each pair running at a higher speed than the preceding pair, whereby the cotton fibres in the sliver are gradually drawn out and laid regularly side by side in continous juxtaposition, ready for being finally spun into thread by the twisting motion of the spinning machine. In the ordinary drawing rollers, the lower roller of each pair, which is the only one driven, is fluted with small grooves cut in its surface by a kind of planing machine, parallel to the axis of the roller; and the upper roller being covered with leather and held down upon the lower by a weight, its softer surface becomes gradually indented or fluted by constantly pressing upon the straight flutes of the lower roller; the cotton fibres are then irregularly stretched or broken in passing between the two rollers, causing the thread spun to become irregular in thickness. The success of the process, however, depends entirely on the uniformity of the thread being constantly maintained; and this grooving of the upper roller has now been successfully prevented by the writer, by forming the grooves on the lower roller in a spiral direction, instead of straight grooves parallel to the axis of the roller, whereby the upper roller bears always upon a number of grooves at the same time, instead of upon a single straight groove. The method of fluting the lower roller has also been improved by the writer, by the substitution of a milling process, indenting the flutes in the surface of the roller, instead of the ordinary plan for planing them out by a cutting tool, whereby the grooves were left with a keen edge and a slight burr, which would catch the fibres of the cotton, requiring a tedious hand process of rubbing down after the grooves had been cut, to finish the roller for use in the drawing machine. The milling is performed by a steel milling tool, with a narrow milled edge, which is the counterpart of the spiral flutes to be formed in the roller; this mill is pressed into the surface of the roller at one end by a heavy weight, sufficient to make it indent the roller; and the roller being made to revolve underneath it, the mill is traversed along the entire length of the roller. The milling is effected very rapidly, and completes the fluting of the roller at one operation, leaving it with a finished surface ready for immediate use in the drawing frame. The distance between the successive pairs of drawing rollers being determined by the length of fibre of the cotton to be drawn, the rollers are required to be closer together, and therefore smaller in diameter, for short-fibred cotton than for long-fibred; and for drawing the shorter-fibred cotton now being introduced from the new sources of supply in India and China, smaller diameters than those hitherto used are required: rollers made of Bessemer steel have accordingly been applied by the writer with advantage, this metal allowing of their being made small enough in diameter for the shorter fibre, and yet sufficiently strong at the coupling socket joints.—Specimens of the milled rollers and milling tools were exhibited, and of the Bessemer steel rollers, with full size working models of the sets of drawing rollers shown in action.

The next Paper read was "On the Locomotive' Engines in the International Exhibition of 1862,' by Mr. Daniel K. Clark, of London. Twenty locomotives altogether were exhibited, of which eleven were English and nine foreign; and fourteen had outside cylinders, and six inside cylinders. Most of the engines were specially constructed for burning coal, a feature which has been introduced entirely since the former Exhibition of 1851, on account of the smaller cost of coal for fuel compared with coke. The English engines were mainly examples of the standard classes in general use on the principal English railways; of the eleven exhibited, seven had outside cylinders and four had inside cylinders. The foriegn locomotives showed greater variety, boldness, and originality of design, and were mainly constructed for lines with very heavy gradients and sharp curves, which are generally associated together on railways in mountainous districts, causing special mechanical difficulties not applying to the cases of the English railways. The most satisfactory of the plans for surmounting these difficulties is considered by the writer to be that of an articulated or bogie engine, having a single long boiler of large dimensions, mounted on two separate carriages, with a swivelling connection, each having its own separate pair of cylinders, working six coupled wheels placed near together: so that the engine, although of great total length, could readily pass round very sharp curves, whilst the whole of the weight is made available for driving adhesion. The other principal engine of this class, the "Steierdorf," in the Austrian department, was a tank engine of very large dimensions, carried on ten wheels, the six leading wheels being coupled together as usual; and the additional adhesion on the rails is obtained by coupling together the four trailing wheels also, which are driven from the leading wheels through an intermediate shaft, with spherical bearings for all the coupling rods, so connected as to allow of the two sets of wheels assuming any angle to each other in running round sharp curves, the engine frame having an intermediate swivel joint for this purpose. A marked feature of the foreign engines is the position of the valve gear outside the cylinders; but this is considered objectionable in respect of good working and durability. In the larger foreign engines also, as well as in some of the English, the boiler tubes have been crowded too close together, with the object of obtaining larger extent of surface, from a mistaken idea that heating surface is mechanically the equivalent of evaporative power, without regard to the equally important consideration of the circulation of the water amongst the tubes; in the extreme instance of 356 tubes, fixed with only 7-16ths inch clear space between them, a large proportion of the tube surface must be practically inoperative for raising steam. Another marked difference between the engines exhibited in 1851 and those shown at this Exhibition is that in the latter Giffard's injectors have been extensively employed as a substitute for the feed pumps universally used at the former period.

The meeting then terminated.

INSTITUTION OF CIVIL ENGINEERS.

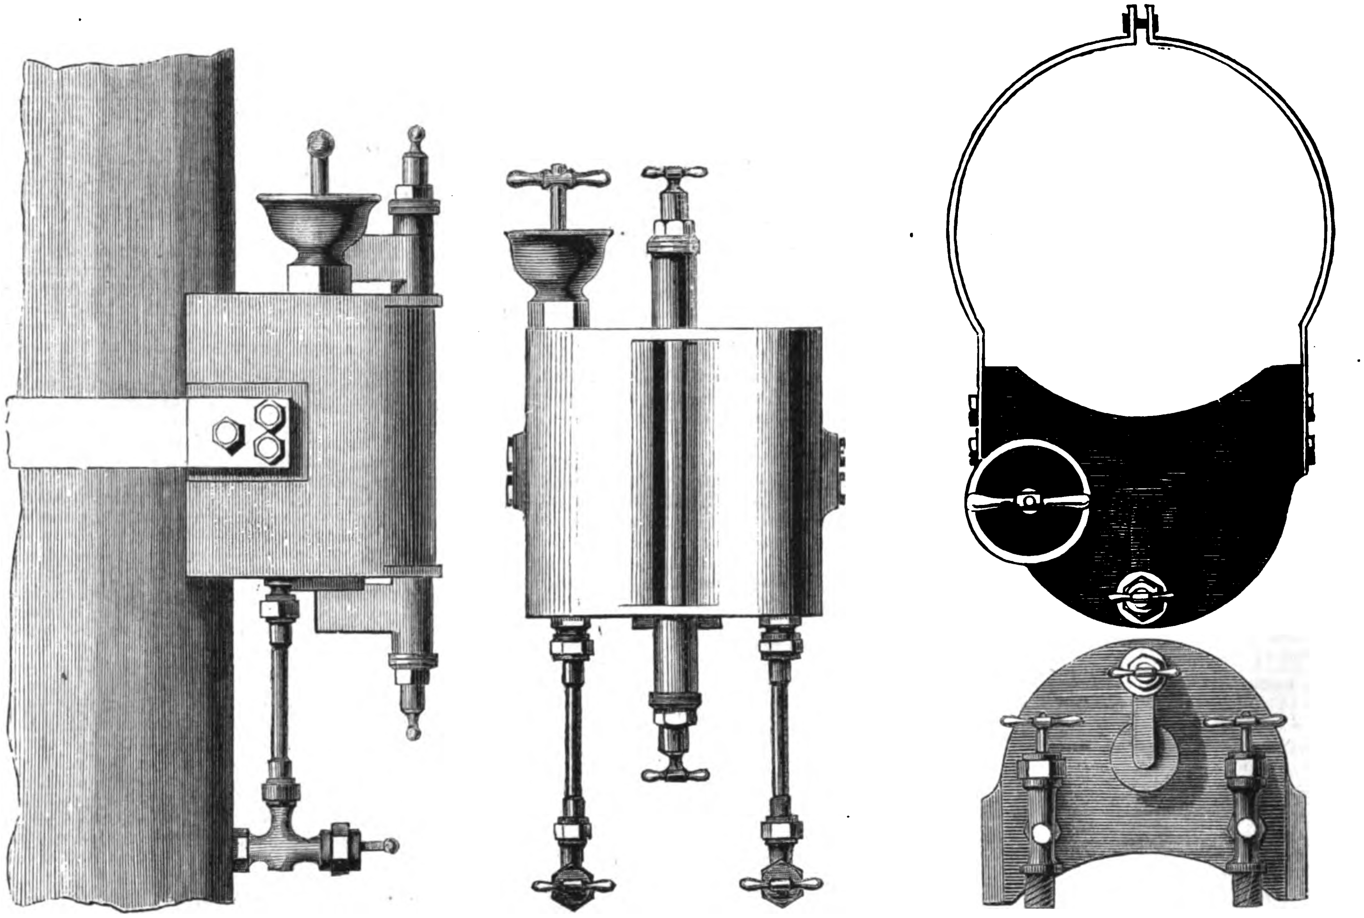
On Cellular Iron Backing to Armour Plates.

At the meeting of the 25th February, 1862, in the discussion on Mr. Samuda's Paper on Iron Plated Ships, Mr. George Clarke made some remarks on iron cellular backing, of which, as the subject is one of public interest, we give a summary, and especially as a target built on Mr. Clark's principle is about to be experimented upon at Shoeburyness. After showing by an analysis of Mr. Samuda's plan that his arrangement for strengthening armour plates was a system of panelling, of which the panels would be 6 in. and the frames 7½ in. in thickness, Mr. Clark said:—We have, then, this simple proposition, the weakest part of the plates being 6 in. in thickness, do they present an effective resistance to the force of projectiles? I think not; from the results of trials I have seen, I believe 100-pounder and 68-pounder shots would penetrate or break through 6 in. of iron unsupported at the back. These panels are placed exactly in the position to be easily punched, a hollow space being left under the part where the force will be most effectively applied. The result will be, to facilitate penetration. If, moreover, the panel be struck, each blow of the shot will have a tendency to curl up the edges, producing the effect termed buckling.

From what I have observed of buckling, and the diversity of opinions on that subject, it appears not to be properly understood. No turning-up of the edges could take place unless the plates were driven in at the centre or one of the ends. In the trials where buckling was most apparent, the backing has been of wood, which not offering sufficient resistance, the plate was crushed into it, and buckling took place. It is worthy of observation that, in all the experiments, the principal damage was caused by the wood backing yielding to the effect of the blows. In the "Warrior" target trial, from the effect of the last salvo, the iron was crushed into the wood in the area of impact, and the ends of the plate was forced upwards away from the backing 1½ to 2 in. But in experiments on plates with a backing of iron, as in the trial of Mr. Fairbairn's target, whenever the projectile struck a plate over the frames, the iron did not yield so much, being only indented. Another remarkable instance of the same effect was exhibited in experiments of the Iron Plate Committee on a plate 2½ in. thick, backed with cast-iron blocks. A 40 lb. shot produced no impression on the plate except an indentation of scarcely half an inch, and then a 100-pounder struck the plate near the edge, and slightly grazed the head of a bolt, which, acting as a wedge, split off a piece of the plate and of the cast-iron backing, but the plate was only indented three-quarters of an inch. I have come to the conclusion that the essential point in armour plating is the backing on which the plates are fixed. If it is of sufficient hardness, rigidity, and strength of structure to resist the crushing effect of shot, the penetrating effect will be reduced to a minimum, and much thinner plates than those now adopted will answer the purpose better. I think attention ought to be turned to that subject more than any other.

The question of backing is connected with that of fastening. Under any circumstances I consider the through bolt objectionable. It is exposed to impact, and, if struck, is a source of damage to the plate, which is weakened by the bolt-holes. Mr. Samuda's arrangement aggravates these objections. He places the bolts in lines along the edges of the plates, having only an inch of iron outside. If a bolt in this position is struck, it will fracture the plate and separate it from its fastening. But the greatest danger to be apprehended is that tendency of a plate to buckle, which, in my opinion, arises entirely from the want of rigid backing all over, and will be the inevitable result of Mr. Samuda's plan. Without an effective fastening there cannot be a perfect system of armour plating. But with an efficient fastening, and a backing of such hardness and strength as to support the plate effectually, the highest degree of perfection might be attained. It had been said that backing of solid blocks of iron was too heavy for a ship to carry. That is true; but I believe a backing might be constructed on the cellular system, presenting the iron edgeways, which would offer an effectual support to the back of the armour plates, and admit of diminishing their thickness considerably. That, in my opinion, is the true system to be followed out to obtain the object in view. In the construction of the cellular backing, the size of the projectile has to be taken into account. The cells should be so much narrower than the diameter of the shot, that at every blow two cells at least should be covered by the impact. With this arrangement there would be such

CLEMENTS, LLEWELLIN, AND JAMES'S SELF-ACTING LUBRICATOR FOR STEAM ENGINES.



a degree of support afforded to the armour plate, that the effect of heavy shot at the highest velocity might be resisted.

From models and drawings I have prepared, I have come to the conclusion that it will be advantageous to distribute the greater part of the quantity of iron to be used as armour in strengthening the backing. Taking the iron and wood together in the "Warrior" armour, we have a weight equal to 6¼ in. of iron all over. By distributing that weight of iron with judgment, reducing the armour plate to 2½ or 3 in., and disposing the other portion as backing in a cellular form—some outside and some inside the ship's skin—we might, without exceeding the weight of 6¼ in., obtain with backing and armour plate together a thickness equal to 20 or 24 in., and by that combination, I believe, the great problem of rendering ships invulnerable will be solved.

CLEMENTS, LLEWELLIN, AND JAMES'S SELF-ACTING LUBRICATOR FOR STEAM ENGINES.

In our number for April 3, p. 255, we described and illustrated an apparatus for supplying a regulated quantity of lubricating material to the inside of the valve-box and cylinder of an engine. The lubricator is fixed to the steam-pipe, and the current of steam is the primary agent. We would refer to the above number for a general description of the apparatus; but, in justice to the inventors, we feel bound to notice several improvements in detail that have been lately made, and which are shown in the annexed engravings. It will be noticed that the air and discharge valves are placed at top and bottom of the gauge glass fittings; while the arrangement of these latter is altered, so as to have the entire range of the glass. Conical plugs and stuffing-boxes are substituted for the common cocks, previously used; and the valves are placed on the steam-tube, instead of on the bottom of the lubricator. For fixing the apparatus, a simple wrought-iron band is made to clip round the steam-pipe.

TESTING CHAIN CABLES AND ANCHORS.

Mr. Laird has introduced a Bill into Parliament for enforcing a test of chain cables and anchors used in the merchant service. This has been several times proposed before, but without obtaining an Act for the purpose. The matter, we believe, does not now require the intervention of Parliament at all; for, since Lloyds have undertaken to prove all chain cables and anchors voluntarily brought to them for that purpose, Government, the India Board, and the Emigration Commissioners have refused to charter any vessel the ground tackle of which has not been tested up to the Admiralty proof, and a certificate given accordingly. This refusal operates hardly less strongly than a compulsory Act, perhaps, indeed, even more strongly. In one case the penalty for non-testing would be, perhaps, a few pounds; in the other case it amounts to a disability involving a loss of the most valuable charters in the shipping trade. It is true that there are thousands of craft which have but little chance of ever being chartered by Government, or the India Board, or the Emigration Commissioners, and these, we might suppose, could therefore dispense with all tests of their cables and anchors. But as the ships to be engaged as transports or as emigrant ships cannot be positively known beforehand, it is almost certain that the majority of ship-owners will desire to prove at least the eligibility of their vessels, and thus sufficient stress will be laid upon this as to induce most, if not all, owners to "qualify" accordingly.

For every ship in the Navy there is a minimum length and size of stud-chain cables, hawsers, and warps, and a minimum number and weight of bower, stream, and kedge anchors. For steamers the chains and anchors need be equal only to those of a sailing ship of two-thirds their total tonnage. Thus, for a 1,000-ton sailing ship, or a steamer of a total tonnage of 1,500 tons, she must have at least 300 fathoms of 1¾ in. stud-chain cable, tested up to 55 1-10th tons, and weighing 23 tons 6 cwt., with three bower anchors of 2 tons each, one stream anchor of 12 cwt., and two kedge anchors, one of 6 cwt. and one of 3 cwt., the bower anchors to bear a test of 35 tons 15 cwt. Lloyds' Committee have adopted the Admiralty requirements, and only grant certificates where these are fulfilled. We may observe here that the Admiralty test of stud-chain cables is 630 lb. per circular ⅛ in. of the diameter of the iron of which the chain is made: thus a chain 1 in. or 8-8ths in. in diameter has 64 circular eighths of an inch, and 64 X 630 = 40,320 lb., or 18 tons exactly. Now the section in the two sides of a 1 in. link is 1·57 square in., and thus this test amounts to a strain per square inch of 11·46 tons, a test which is the same per square inch whether the cable is ¾ in. or 3 in. in diameter. The breaking strength of good cable iron may be taken as from 24 tons to 27 tons per square inch; but, even with iron of this quality, the link, when made up, generally breaks at about an angle of 45 deg. with its own axis, and under a strain not often more than two-thirds of that which would have broken the two sides of the link before it was made up. This 1⅛ in. iron, of the strength of 27¾ tons, often breaks, when made up into a stud-link, at 43 tons, instead of at 55½ tons, the sum of the original strength of the two sides. And as such a cable, 1⅛ in. in diameter, is tested up to 22¾ tons, this, it will be seen, amounts to more than one-half of its actual breaking weight. Open-link chains are proved to but two-thirds of the strain of the stud-link, or cable chains.

The proving-house of Lloyds' Committee was erected last year under the superintendence of T. M. Gladstone, C.E., in the New-road, Poplar, contiguous to the West India Docks. Heretofore chain cables have been tested in lengths of 12½ fathoms only for the Navy, and 15 fathoms for the merchant service, these lengths being afterwards connected by shackles up to any length required. Mr. Gladstone prefers, however, to prove from 60 to 75 fathoms at a time, and the proving house, of galvanized iron, is nearly or quite 500 ft. long. At the southern end are the offices, weighing machine, hydraulic press, and pumps. A railway extends the whole length of the building, and there is also an iron trough, about 18 in. deep, running the same distance, and in which the cable is placed when under strain. All the mechanical operations of handling and proving chains and anchors are performed by a steam travelling apparatus, designed by Mr. Gladstone, and called the Dromedary. This a substantially made steam crane, mounted upon a four-wheeled truck, and, furthermore, provided with means for its own propulsion as a locomotive, and also for underrunning cables, and for driving a set of hydraulic pumps. As a crane, this machine will lift, swing, and lower 10 tons. Stationed near the pumps, and working through a universal joint, it will, in a few minutes, get up any required strain up to 300 tons in a length of 73 fathoms of cable, and in other ways it is so serviceable that but six or seven men, including engineman, smith, and labourers, are employed in the entire work of bringing in a cable or anchor from the docks, and testing, repairing, and delivering it again. The cost of the Dromedary, we are informed, is but £650. The cable is hauled out of a barge afloat by a light windlass, and coiled upon a truck. This is taken by the Dromedary into the proving-house, and slowly down the line of rails abreast of the trough in which the chain is to be laid for proof. During this journey of the truck, which occupies but a few minutes, over the distance of 450 ft., the cable is let off, by the same light windlass, and deposited upon the floor. A large broad-grooved sheave, suspended from the jib of the Dromedary, is then got under the cable, and with the sheave properly adjusted in its position, the Dromedary underruns the whole length of 75 fathoms in about 9 min., thus hoisting the cable into the trough without its being touched by hand. The trough is nearly or quite 2 ft. wide, and has iron sides of a total section of nearly 60 square inches. These are fastened by stout flanges at the bottom to the heads of piles, driven deeply into the "made ground." At every 15 fathoms there is a cross-bar, so that 15, 30, 45, 60, or 75 fathoms may be tested as required, the longer lengths being preferred for convenience. The cable, being made fast at one end to one of the cross-bars of the trough and at the other to the cross-head of the hydraulic press, is ready for testing. The hydraulic press is horizontal, and forms one end of the trough. It has a bore of 16 in. and a piston rod of 8 in. diameter, the annular area for pressure being thus about 150 square inches. The press cylinder is long enough to allow of a 10 ft. stroke. The highest intended pressure is 2 tons per square inch, equal to total strain of 300 tons, but the 2¼ in. cables of a 3,000 ton ship require a proof strain of but 91 tons, and the proof of even the "Great Eastern's" cables is but 167 tons. The permanent friction of the press, which friction is not much affected by the pressure to which it may be worked, is 11 cwt., and it is seldom that a greater pressure than half a ton per square inch requires to be applied by the pumps. The Dromedary being run up alongside these, and a universal joint slipped upon the pump-shaft, the pressure is quickly got up. A machine for exactly weighing the strain applied is fixed in a room near by, and from which there is a view of the whole length of the cable. The pressure of the water is received through a small copper pipe upon the end of a gun-metal plunger ¾ in. in diameter, attached to a scale beam provided with moveable weights. The strain is increased until the scale beam rises under the proof weight, when the cable is struck four or five smart blows with a sledge hammer at about the middle of its length. No accidents have yet happened to the workman striking these blows; but we should suggest a falling weight, to be released by a trigger tripped by a long cord. The strain is kept on three or four minutes, during which the cable is carefully examined throughout. When breaks occur, it is almost always at a weld, and a large number of links never welded through one-tenth of their cross section have already been found since the proofs commenced last November. A large mooring link made by a first-class firm for the Peninsular and Oriental steamship "Poonah" was broken the other day at an imperfect weld. Many cables go, at every 15 fathoms length, almost as soon as the least strain is put on. When the cable breaks in two the broken ends draw apart within the trough, and it is seldom that a fragment of a link flies out, in which case its course is upward, owing to the form of the trough. The roof of the proving-house has not yet been hit, however. Broken links, if not too frequent, are welded up again at the owner's expense. The forge for this purpose is mounted upon a light truck, and is thus moved to the work instead of bringing the work to the forge. When the cable has been tested, it is underrun from the trough and coiled upon a truck, and taken away by the means already described. The charge for testing, examining, weighing, and certifying chains is 10s. per ton, with an increased rate for chains under 1 in. For re-testing the charge is 5s. per ton. Anchors are tested at a charge of 10s. for each arm. Links are repaired at a fixed scale, according to diameter. If a chain will not bear the Admiralty strain on the third testing, a certificate will be given up to within 10 per cent. of the breaking strain if required. The test for an anchor is about two-thirds that for its corresponding cable, and no anchor is certified if the permanent set of one arm exceed ¼ in. The details of the proving establishment are exceedingly simple and effective, and do much credit to the engineer, Mr. Gladstone.—*The Engineer.*

IRON BRIDGE MAKING IN WORCESTER.

A new description of manufacture, says the *Worcester Chronicle*, has of late been developing itself in this city, namely, that of iron bridge-making for railways and other large works. Messrs. M'Kenzie, Clunes, and Holland, of the Vulcan Works, near the railway station, mechanical engineers, have latterly been manufacturing such bridges on a very extensive scale. By means of a first-rate plant, and machinery of the most scientific character, this energetic and enterprizing firm seem to have succeeded in naturalizing, in this city, a species of manufacture usually thought to belong specially to the mining districts, and give employment to between 300 and 400 hands. One of the works just executed at the Vulcan Works is an iron bridge intended to carry a railway across the river Spey, in the north of Scotland. This is the Morayshire Railway, which communicates with Elgin and Lossiemouth, and forms a junction with the Strathspey line at Craigellachie. The bridge is constructed to have four openings, or waterways, one of which, 200 ft. wide, forms a passage for the river, and the others, which are each 57 ft. span, are to carry off the floods which often occur in that district. The bridge altogether approaches 400 ft. in length, but is only 17 ft. in width, the railway having only one pair of rails at this point. The bridge is built upon what is called the "lattice-girder" principle. The framework of each girder is made of the stoutest boiler-plates, and the interstices of the framework are filled in with strong bars of angle-iron crossing each other diagonally, and thus forming a gigantic lattice-work. Hence the name of this kind of girder. The portion of the bridge intended to cross the Spey being the most important portion of the work, was put together in the yard of the Vulcan Works, and attracted the attention of all who passed along the road by its great size and singular appearance. Had it been covered in at the top, it would have resembled somewhat a tubular bridge with lattice-work sides, but sufficient strength for a span of 200 ft. was obtained in the two girders, which stood up like enormous balustrades to the height of about 18 ft. These were kept in position by means of what are called "diaphragms," which stretch across the roadway of the bridge from girder to girder, with wide openings in them to allow for the passage of trains. There were five of these diaphragms strongly bolted to the most substantial portions of the framework of the girders, so that with machinery sufficiently powerful, the lifting of one portion of the work would have been the lifting of the whole. The floor of the bridge ran nearly in a straight line from abutment to abutment, with very slight rise. The rapid manner in which the machinery punched out the rivet-holes in the stout metal, which seemed but as so much paper undergoing the operation, was looked at with some astonishment by the spectators, and the speed with which the iron fabric grew in size, from day to day, was equally a source of wonder. The bridge has now been removed, and we believe is by this time fixed in its intended position over the Spey. It is to be supported by strong abutments capped with iron; and an arrangement of friction rollers is contrived to allow the various lengths of the bridge to expand and contract by heat and cold, without injuring these abutments. The ironwork of the bridge weighs about 300 tons, and by the contract was to bear a tensile strain of 20 tons to the square inch; this, it it is said, was considerably exceeded. Having provided a bridge for the accommodation of the Morayshire travellers, the same firm is now, we believe, engaged upon one for those of Wales. This is to carry an ordinary road over a creek or estuary, and by forming a junction with two turnpike-roads —Abergele and Rhyl—will save a wearisome detour of about 14 miles. This bridge is also on the "lattice-girder" principle, and will span four openings, three of which are 76 ft. wide, and one 40 ft. The portion of the bridge above the 40 ft. opening will be constructed to draw back, as at our Upton bridge, to allow of the passage of vessels on the water. The bridge will be supported by iron piles, and will be 21 ft. wide. The roadway will be of wood, covered with road metal. The junctions of the four lengths of the bridge will be finished off with cast-iron pilasters of an ornamental character. In this bridge about 122 tons of wrought iron will be consumed. The engineers for this bridge, which is built for the Rhyl Bridge Company, are Messrs. Piercy and Hughes; and the contractor is Mr. Savin, who, like Mr. Piercy, is well known in the Welch districts for his extensive railway operations. The engineers of the Morayshire bridge are Messrs. Samuel and Mills. The boiler plates and angle-iron for both structures were supplied by Messrs. J. and F. Hall, the well-known ironmongers of the city. Lest our speaking of Messrs. M'Kenzie, Clunes, and Holland as having devoted their attention to bridge-making may lead to misapprehension as to the nature of their manufactures, we think it right to add that there is nothing within the ordinary range of mechanical engineering which they do not execute. Among the great variety of articles which they turn out are considerable numbers of metallic piston rings, made under the patent of Mr. Edward Wilson, of the West Midland Railway. We saw the other day at the Vulcan Works a set of these nicely-adjusted metal hoops, intended for the engines of one of the largest steam frigates in Her Majesty's Navy.

MALLET'S FOLLY.

One of the most promising objects in or near Dublin was "Mallet's Folly," a huge oblong building standing on the north bank of the Royal Canal. It was built by an Irishman named Mallet, who signally failed in his speculations. Since then "Mallet's Folly" has been falling into decay, and for a long time has been the home of bats, swallows, and the ivy. Messrs. Murtagh Brothers have recently restored the building in a most remarkable manner, and what was known as "Mallet's Folly," is now known as the "North City Flour Mills." The internal arrangements, says the *Freeman's Journal*, are most complete, and calculated to give on inspection much pleasure to all interested in mechanical engineering. The several departments on the lofts are admirably arranged for their purposes, and the means by which the steam and water power is distributed to do all kinds of work in different localities is most simple and ingenious. The water power amounts to about 40 horse (nominal) and the steam to about 200. It would be an arduous and lengthy task to enter into anything like a description of the several departments of this great concern; but it will be sufficient to say that it is in every way one of the finest establishments of the kind in the kingdom. At present, the machinery is working 19 pairs of millstones, and provision has been made for 40 pairs at full work. Although the waters of the canal flow at the base of the North City Mills, the Messrs. Murtagh have adopted the wise precaution of having a plentiful supply of water at a high pressure. To effect this great object they have got an iron tank erected on the top of the building 4½ ft deep. This tank is capable of containing over a million gallons of water, and is constantly kept full by the engine. On each loft a cock and screw is affixed to the down pipe, to which, in case of fire, a nozzle hose could be attached, and extinguish even a formidable blaze in a moment. A large towering furnace chimney recently built at the mills, is the highest in Dublin. Some extensive machinery has been constructed and erected by J. Rowan and Sons, York-street Foundry, Belfast. It is a magnificent specimen of a single condensing engine, and the largest in Ireland. To see it in its ponderous and majestic strength doing its work would well repay a visit. Some notion will be formed of its magnitude when it is known that the fly-wheel is 28 ft. in diameter, and the driving wheel 25 ft. Its length of stroke is 7 ft. The cylinder is what is known as "45 in.," and the engine is capable of working up to 200 horse, at the low pressure of steam on the valves of 25 lb. to the square inch. It is furnished with Rowan's patent double-beat valves, and "fluctuating patent slider" which acts in concert with the governor to cut off the steam at any point of the stroke according to the load; and, as a specimen of engineering and skilled manufacture, it could not be surpassed by anything produced in any other country. The two circular horizontal boilers are furnished with double furnaces, and supplied with Rowan's superheating apparatus. The consumption of fuel to sustain the above-named pressure for twenty-four hours is within 50 cwt. of common coal. The machinery is finished in excellent style, and in keeping with the whole establishment, which, we have no doubt, will soon illustrate how native commercial spirit and enterprize will turn

"Mallet's Folly" into profit and wisdom, and teach a lesson to all Irishmen to be self-reliant, true to themselves and to one another, and to leave no "Mallet's Folly" at which the finger of the scorner can point.

HYDE'S PATENT FLOATING BATTERIES.

MR. J. HYDE, of New York, U.S.A., has recently obtained a patent in this country for an improvement in floating batteries. The invention consists in the employment of a shot-proof turret, as represented at figs. 1 and 2 in the accompany engravings, and so arranged as to float in water contained in a suitable reservoir or compartment formed within the ship's hull, the centre shaft of which is sustained by hollow frames, forming at the same time a communication between the inside of the ship and the inside of the turret by a suitable passage way through the hollow frames and through the central shaft, and also in the arrangement of the gun running on curved railways. Near the centre of the ship's hull a reservoir or compartment is formed, nearly filled with water or any other suitable fluid, in which floats the turret or gun-house. A hollow arch-like frame extends from the hull over the turret, from which projects downwards a hollow shaft, into the lower end of which a stud or shaft is fitted, capable of sliding freely up and down, and connected to one of the floors or decks of the turret through a universal joint. A system of gearing is arranged around the lower part of the hollow shaft and connected with the central stud, whereby the same, and consequently the turret, can be turned or rotated in the reservoir. By virtue of the universal joint, the turret is also free to tip in any direction, in consequence of which the careening of the ship will not affect said turret so much, the tendency of the water in the reservoir being to maintain its level, whereby the turret is caused to float in a level condition, while the hull tips, whereby a greater degree of accuracy can be obtained in firing the guns than can be arrived at in the present mode of construction.

The guns are made to travel on circular railways, as clearly shown at fig. 3, in the shape of a quarter of a circle, the carriages being constructed with suitable sector frames, which are hung at one end on pivots fastened to the deck around which the carriages travel. By this arrangement less space is required for the guns, and consequently a greater number of guns can be arranged in one turret, and capable of being fired directly opposite each other. Suitable elevators or dumb waiters are arranged in the turret through which the ammunition is passed up from the lower decks of the turret to the guns, as may be required.

THE EFFECT OF SHOT ON THE "NEW IRONSIDES."

THROUGH the attention of an officer on board the "New Ironsides" we are enabled to present our readers with a diagram of the effects of the rebel shots which were fired at that vessel during the recent attack on Fort Sumter. The injuries were very slight; the vessel was struck in all about ninety times, we are told, but the most serious damage she received is here depicted. Previous to describing the diagram we will let our correspondent tell his story in his own way:—

"MESSRS. EDITORS.—We have had a fight with Fort Sumter and Moultrie; but as there was a reporter for one of the New York papers on board, I will not go into a description of it, except to speak of the effect of the shot on our plating. In reference to the 'Keokuk,' I will state, primarily, that I was informed by one of her crew that she received 89 shots through her plating, 15 of which were below the water line, also that a 32-pounder pierced her bow. The 'New Ironsides' received very little injury; the worst being the loss of one of the iron port-lids; it was knocked off by a rifle shot supposed to have been fired from Fort Moultrie. I examined the iron, and it appears to be crystallized, as the break was short off, although it was in the weakest part. Our plating stood the test very well, as the shot that struck seem to have broken into pieces. There was a rifle shot taken out of our stern, where it had buried itself in the wood. Enclosed please find a rough sketch of some of the marks which the 'New Ironsides' received."

Fig. 1 is a representation of a spent rifle shot found in the wooden stern of the ship after the engagement. The body of the shot is 6 in. in diameter and 10 in. in length, and is, as the reader will discover, a most formidable instrument for offence. The bands at the base and the forward end produce—the one, the necessary rotation to the missiles by expanding into the grooves; the other centres the shot in the bore of the gun, so that its flight will be true after leaving it. The piercing end of the missile is rounded, and it is in all respects the very counterpart of those projectiles which inventors at the North have experimented with and proved to be the most effectual against armour; thus showing conclusively that the rebels have full and early intelligence of every mechanical novelty of merit. Fig. 2 is a section of the inclined armour of the "New Ironsides," showing the indentation of the shot at A, and also the wooden backing of the plates at C and D. The shot broke in pieces and flew off without penetrating or disturbing the backing, although it came very near it. Fig. 3 is a view of the broadside of the ship, and shows several scars. The port-lid A was broken off, and lost overboard, by being struck at B, near the point of support, by a rifle shot. The plate E was struck by a round shot at D, which cracked the armour in the line C; the shot made an indentation 1 in. deep by actual measurement. The fractured port-lid was also struck, before it was finally detached, by a round shot at F. The shot carried away the edge of the lid, and, striking the main armour, glanced off and made the long "blaze" at G. The plate H was struck at J by a rifle shot, which glanced off after breaking the plate on the line K, also scarring the timber backing: the armour ends at that point. One rifle shot also struck on one of the bolts that hold the plating to the ship, and made an impression $2\frac{1}{2}$ in. in depth. Some of the rifled shell of the enemy entered the "New Ironsides" bow, but were prevented from doing any damage by the precaution of the commander in placing sand-bags at that point. Without this protection the shells would undoubtedly have done considerable damage. The ship ought to be as completely iron-clad as the "Roanoke" is. She would then be more effective against an enemy than in her present condition. The "New Ironsides" is not completely iron-clad, but only on those points covering her broadsides; the bow and stern are left undefended, as in some of the English vessels. She took an active part in the fight at first, but afterward fell back out of range, being unmanageable. The channel is tortuous at that point, we are given to understand, and the ship could not obtain sufficient momentum to get

GREENWOOD'S STAVE-CUTTING MACHINERY.

FIG. 2.

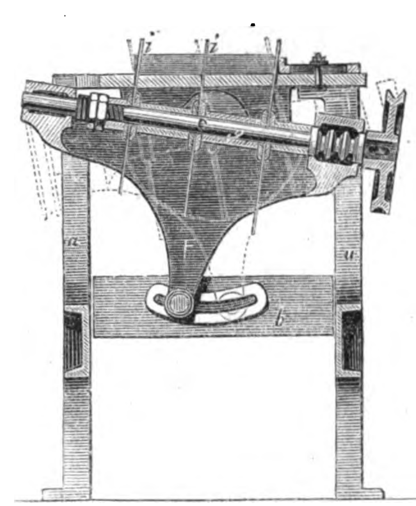

FIG. I.

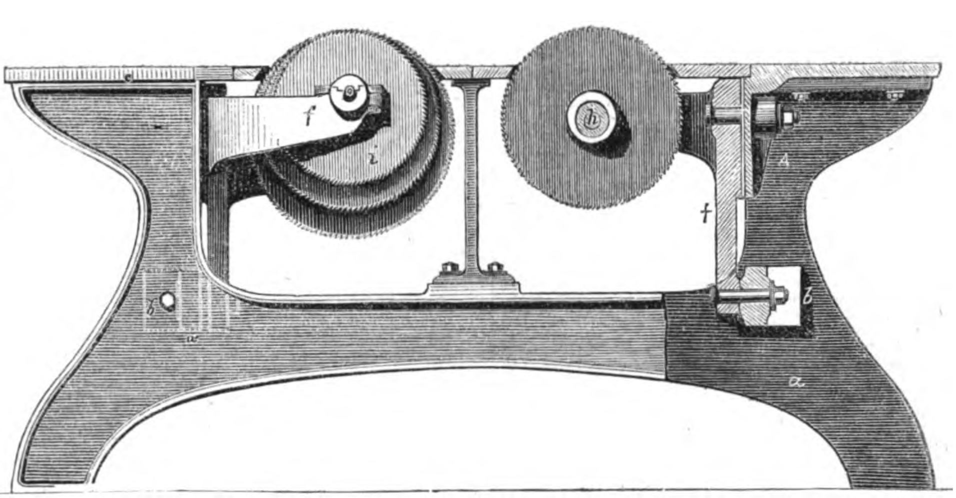

steerage way on her. We are unable to say at what range the rebel shot took effect on the "New Ironsides," nor do we know what charges of powder propelled them. That they struck at a low velocity, however, must be inferred from the fact of the rifle shot sticking in the woodwork. The ship was also unable to deliver her broadsides with good effect, and fell back as before stated. When all things are more propitious than on the last occasion, we do not doubt that the ship and the brave fellows who command and man her will give a good account of themselves.—*Scientific American.*

EFFECT OF SHOT ON THE "NEW IRONSIDES."

FIG. I

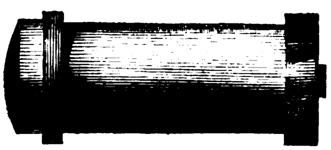

FIG. 2.

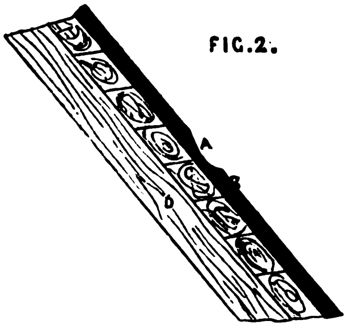

FIG. 3.

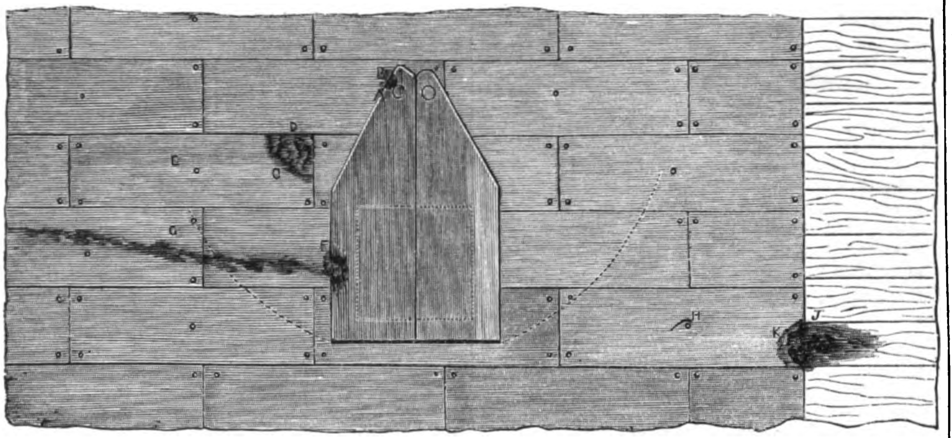

GREENWOOD'S STAVE-CUTTING MACHINERY.

The accompanying engravings illustrate an arrangement of machinery for cutting staves for casks.

The object of this invention is to facilitate the operation of cutting or shaping staves from planks of wood, such staves being intended to be applied as a cylindrical covering for metal casks, and for analogous uses. The wood is submitted to a sawing machine, which at one operation will cut the bevelled edges of the staves. The machine is provided with a double set of oblique saws, the shafts of which are inclined in opposite directions, but at the same angle; and for the purpose of bringing the cutting edges of each set on a level, or nearly so, the saws are made of varying diameters.

In the accompanying engravings fig. 1 is a side elevation, partly in section, of the improved machine; and fig. 2 is a transverse section of the same. *a a*, are the side frames of the machine coupled together by cross-bars *b b*, and by plates *c*, which form a portion of the table of the machine. These plates are cast with pendent pieces, which are faced up to receive each a swing bracket *f*. The brackets are cast with arms to embrace and carry the saw shafts *g* and *h*, which turn freely in suitable bearings provided to receive them. That portion of the brackets which is in contact with the pendent pieces is also faced up to ensure close contact between the parts for the purpose of obtaining steadiness in the brackets. The brackets are carried by fulcrum pins, which pass through the pendent pieces, and are tightened up by nuts on their outer ends. The lower end of each bracket is furnished with a screw bolt, which enters a segment slot in the cross-bars *b b*, and receives a nut for clamping their respective brackets in any required position. Mounted on the shafts *g h*, are the sets of saws *i i*, the one consisting of an odd number of saws, and the other of an even number for a reason that will be presently understood. These saws project through slots made in moveable plates (forming portions of the table), in order that they may reach their work, which is moved forward over the table. For guiding the wood up to the cutters the table is provided with an adjustable guide.

It will now be understood that any amount of obliquity may be given to the saws by simply slackening the screw bolts, and moving the saw shafts to the required angle, and then clamping them to secure them in their new position. The change of obliquity is needed to suit various kinds of work, it being understood that as the wood is brought up and fed past the first set of saws while the same are rotating, oblique, parallel or bevelled cuts will be made through the wood in one direction, the angle of the bevel corresponding to the obliquity of the saws. After passing the first set of saws the wood will come under the action of the other set of saws, and these being mounted obliquely in the opposite direction, and at a corresponding inclination, will cut the opposite bevel for the staves, dividing the already severed portions of the plank equally down the middle. When the saws are intended to be set at an extreme position, it may be necessary to change the table plates for others whose slots will not interfere with the saws taking the new angle of inclination desired to be given to them. By reference to fig. 2 it will be seen that the action of this machine is to cut the wood into bevelled staves in a manner that will give waste pieces only at the edges of the plank. The saws, it will be seen, are mounted in the usual manner on their shafts, and they are at equal distances apart, the relative positions of the saws of the two sets being such that the second set which comes into action will divide the severed portions of the plank evenly down the middle. The saws driven by bands from any prime mover, pass over pullies on the ends of the shafts. For presenting the wood to the saws and holding it firmly under the action of the saws, any suitable or well known contrivance may be adopted.

It is reported that a party of travellers have succeeded in discovering the sources of the Nile.

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisments.

All communications should be addressed to the EDITOR, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

RECEIVED.—V. P.—A. G.—W. P. M.—B. H.—J. N.—A. G.—G. C.—J. C.—J. A. D.—T. H. and Co.—Prof. T.

W. K.—We could not co-operate with you in the matter.

J. A. DAVIS.—In our next.

T. L. M. (Belfast).—The work that will probably suit your purpose best, is the "Treatise on Cast and Wrought Iron Bridge Constructions," by William Humber. (E. and F. N. Spon, Bucklersbury, 1861.)

S. M.—We are always most willing to give any advice in our power, and you may rely on our good faith, if you think it desirable to show us your scheme.

T. F.—We would refer you to a review of Hopkinson's Work on the Indicator, in a late number; in that article you will find most of the rules for calculating the horse-power of steam engines.

T. L. (Bradford).—Before your invention was provisionally registered, you would have some difficulty in selling it, as you would have to explain the scheme to anybody desirous of being a purchaser. Save up your money, and in the mean time, by careful study and thought try to ascertain the true value of your idea; you could then patent it or provisionally register it yourself.

EXQUIRER.—Arthur Woolf was not the inventor of the "compound," or the combined high and low pressure engine. This can be proved by referring to the old specifications of Hornblower and Roberton.

Correspondence.

◆

THE CHALMERS' TARGET.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—The experiments at Shoeburyness are a national institution. Their object is to determine the best system of attack and defence in naval and military warfare. Upon them will greatly depend the safety and independence of the country. It is of the highest importance that the experiments should be properly reported and correctly appreciated; and, above all, that the conclusions drawn from them should be practical and sound. The phenomena exhibited at the recent trial of Mr. Chalmers' target are so remarkable they deserve especial notice. Your report shows that his system is stronger than any other system to resist penetration, but weaker to resist smashing. It is interesting to examine the causes of these apparently contradictory results.

In the structure which constitutes the Chalmers' target, the peculiar feature to which the success obtained is due is the rigid backing. It is composed of alternate horizontal layers of teak planks and iron plates, the former 11 in. wide and 4½ in. thick, the latter 11 in. wide and ⅜ in. thick. This arrangement, in principle, is an iron cellular backing, the cells being formed by the edges of the ⅜ in. iron plates abutting against an inner 1¼ in. vertical plate. The teak planks are the filling to the cells.

The inherent weakness of this mode of construction is obvious. The ⅜ in. iron plates having no flanges, are not riveted or otherwise fastened to the back plate, they only abut against it with their edges; and they, as well as the teak planks, are simply piled one on the other. The designer, to unite these loose parts, has recourse to the expedient of tying the planks and iron plates together vertically, by means of 1 in. iron rods with screw ends and nuts; and he fastens the backing horizontally with bolts through some of the planks screwed up inside the skin. He also uses marine glue to cement the parts together. In this plan, there is an evident want of cohesive strength. For the passage of the vertical rods, numerous holes are perforated in the planks and plates forming the backing, of which the strength of resistance to smashing force is thereby greatly diminished. On the other hand, the horizontal bolts through some of the teak planks afford but a feeble hold to the ship's hull. The armour-plate bolts do nearly all the work of maintaining the backing in its place. This, on a ship rolling in a heavy sea, would be a serious defect. The backing ought to be securely fastened to the ship independently of the armour plates.

Another source of weakness is the teak planking interposed as a "cushion" or elastic medium between the backing and the ship's side. This coating of wood, 4 in. thick, is a break in the continuity of rigidity. The resistance offered by the iron cellular system ceases at the line of contact with the teak "cushion," which being a yielding material, must be crushed in if the projectile force is sufficient to penetrate the outer armour plate.

The correctness of this view is proved by the tremendous smashing effect on the target of the 300-pounder shot fired with a charge of 45 lb. The destruction in this case was far greater than that produced by the same projectile force on the "Warrior" target. The shot passed clean through the Chalmers' target unresisted, and then struck against a 9-inch solid iron Hawkshaw target in the rear, with so much force as to burst it open behind. But at the "Warrior" trials, it will be remembered, that two or three of these heavy missiles encountered so much obstruction from the solid teak backing, they were stopped by the iron skin, and did not penetrate into the inside of the ship. This remarkable difference must not be lost sight of. It is accounted for by the frail nature of the structure composing the Chalmers' backing.

But, nevertheless, it must be acknowledged, that rigidity of backing has achieved a great success. Plates 3¾ in. thick resisted penetration from 110, 68, and 200 pounder solid shot fired singly and in salvos at 200 yards, better than 4½ and 5½ inch plates at any former experiments. The amount of buckling was comparatively small, and consequently the bolts were not strained. The salvo of 5 guns destroyed seven or eight bolts of the "Warrior" section; it broke only one of the Chalmers' target. The result in the former case, and the damage to fastenings generally, in other experiments, are to be attributed, as I have often pointed out, to the distortion of the plates arising from their being bedded either on wood or an iron skin without backing.

The result of the experiments on Monday last goes far to prove the efficacy of rigid backing; but to obtain its full amount of resistance, in proportion to the weight of materials, the principle must be carried out to its full extent in combination with perfect cohesion of all the parts of the structure.

The extra weight of Mr. Chalmers' target must also be taken into account. The following calculations show that the armour outside the ship's skin weighs full 60 lb. per superficial foot more than that of the "Warrior," and about 70 lb. more than that of the "Minotaur."

WEIGHT OF MATERIALS IN THE CHALMERS' TARGET.

	lb. per sq. ft.
Outer armour plate 3¾ in. thick .... =	150
Inner do. 1¼ do. .... =	50
Teak 15 in. thick .... 15 in.	
less 10 per cent. for thickness of the ⅜ in. iron plates = 1·5	
inches .... 13·5	
13.5 in. = 1.125 cubic feet at 48 lb. =	54
⅜ in. plates 11 in. wide and 5 in. apart equal to 1 in. all over .... =	40
Vertical 1¼ in. tie-rods, backing, bolts, and washer blocks equal per foot to	20
	314

WARRIOR ARMOUR.

Armour plate 4½ in. .... = 180 lb.	
Teak 18 in., or 1.5 cubic feet X 48 = 72 lb.	
	252
Excess of weight in Chalmers' target per ft.	lb. 62

In these calculations, the armour-plate bolts and the ship's skin and frames are not taken into account on either side. If they were, the excess in the Chalmers' target would be 12 to 15 lb. more. The skin is the same, ⅝ in. thick, in both. His bolts being 2¼ in., whilst those of the "Warrior" are 1½ in., the former with the nuts and washers weigh nearly double, and his frames being 18 in. whilst those of the "Warrior" are 22 in. apart, and he having, moreover, two double frames at the centre, the total number of frames in his target is 10, whilst for the same length (13 ft. 4 in.), the number of "Warrior" frames is 7. It may then be fairly stated that the Chalmers' exceeds the "Warrior" target in weight by 60 lb. per square foot. This is equal to 1½ in. increased thickness of iron all over, and ought to give much greater strength of resistance than the former. Nevertheless, as the trial proved, its resistance to smashing effect is considerably less.

As to the "step-necked bolts," it is impossible to determine whether they contributed to the result obtained. The heads have less holding surface than a conical head, and are more likely to sheer off. The truth, probably, is that the rigid backing preventing distortion of the plates, the bolts were not strained and consequently less liable to be broken or damaged.

When the armour plates are removed it will, no doubt, be found that in the region of the impact of the two salvos, the loose compound of planks, and thin plates, is crushed into the cushion or coating of teak against the skin. Unless that were the case, the frames, it is to be presumed, could not be bent inwards out of the perpendicular to the extent they are, for the force of the salvos, unless it had crushed through the backing and reached the skin, could not have produced the local effect exhibited by the arching of the frames.

There is another point in the construction of the Chalmers' target, giving it an immense advantage over the "Warrior," or any other target tried at Shoeburyness. The height between the deck beam shelf or bearing plates is only 5 ft. 7 in. out of 10 ft. (the height of the target), so that more than 2 ft. of the top and bottom have a solid support, imparting greatly increased rigidity and resisting force to the whole structure.

There is no foundation for Mr. Chalmers statement that his system of backing adds to the strength of the ship. The contrary is the case. The continuity of cohesion, as well as of rigidity, is entirely broken by the "cushion" of wood. The cellular backing, *per se*, is fastened to the skin only by the horizontal bolts through the teak planks. If the armour plates were removed, the entire backing might tumble off from a ship rolling and pitching at sea. The vertical tie rods are mechanically an inefficient contrivance. It could not, moreover, be applied to curved surfaces, and is therefore inapplicable to the sides of a ship.

The real merit of the Chalmers' target is the cellular backing, which, misapplied as it is in his form of arrangement, nevertheless proves the immense value of the rigid principle, which I have so often advocated in your journal.

It may be fairly contended that the experiments on iron armour with wood backing have led to erroneous conclusions, especially with regard to the size and joints of plates. With a perfectly rigid backing and perfect rigidity of cohesion, it will probably be found that smaller plates will resist better than larger ones, and that plates of 3 in. or 4 in. in thickness will do their work more efficiently than plates 6 in. or 7 in. thick with wood backing.

These are considerations of importance in an economical point of view. They are receiving the attention they deserve from Government, and will be solved in a few months by a series of experiments on a large scale, for which preparations are in progress at Shoeburyness.

CIVILIAN.

OCEAN TELEGRAPHY.

SIR,—I should be glad to enter more fully on the subject of Ocean Telegraphy, which the letter of "H. K.," in your last number, would seem to invite, but I have not the time at my command to give that attention the matter requires; and an ill-considered opinion is worse than none, and would only lead to such interminable arguments as to tire your readers without benefiting the cause.

"H. K." proposes a scheme to support an oceanic telegraph cable on submerged buoys, and he invites my opinion, which I give, by saying that I consider it impracticable, and state my reasons for so believing; but he is not satisfied, and seems to cavil at every word. I will, however, endeavour to set the matter of floating or suspended telegraph cables at rest, even to the satisfaction of "H. K.," and that without altering the grounds of my argument, viz., "the insuperable difficulty attending placing the buoys."

In all mechanical and engineering ploblems, when we speak of things being impracticable or impossible, it must of course, be taken for granted that the present state of our knowledge in science and mechanics is considered; for rash indeed would be the man that, with the wonders of science and skill of the present day before him, would deem anything impossible; but I am more warranted in using the word in the present case, as it is not a matter of science and engineering, for, did my life depend upon it, I would prefer trusting the mooring of the proposed buoys to a good boatswain than all the combined scientific and engineering skill in England.

"Britannia rules the waves," and the schoolmaster afloat soon found out she did not rule them straight. Admiral Fitzroy, with all his skill as "clerk of the weather," could not insure a fortnight or three weeks' dead calm between this and America—if "H. K." can, it is another matter; but with the ordinary course of nature, I will give an idea of the "modus operandi" that would have to be be taken to carry out "H. K.'s" project; but, before proceeding, I will observe that Captain Selwyn is right—one ship must of necessity carry telegraph cable, buoys, mooring anchors, and cables, even though all the fleet of Great Britain were placed at the disposal of the telegraphic engineer; and the reason is obvious—wind and sea will often prevent any communication between two ships, without which, were the buoys in one ship and the cable in another, the two could not be united.

The ships have met in mid-ocean or straight, they wait for a fine day to commence operations, and at last secure one; a good sounding is obtained, say 2,300 fathoms; the surface current is tried ("H.K." grants that), one of half-a-knot is found. The sounding lead has taken one hour to go down, consequently the ship or boat taking the sounding has drifted in that time 500 fathoms. Given the rate of descent of each 100 fathoms and the rate of the surface-current required, the reduction to be made from quantity of line run out, for depth—we will guess (for there is no rule by which it can be ascertained) and deduct 250 fathoms, which is near the mark, that the actual depth is 2,050 fathoms. We will keep the boat moored to the sounding line, so that the anchor shall be let go on the same spot as nearly as possible—the buoy is ready, anchor let go, chain or hemp cable (whichever "H. K." pleases)—as it runs out, it is bent to the buoy at 2,000 fathoms. The telegraph cable, in the mean time, is successfully spliced and attached to the buoy. The buoy and cable dissapear, whether to go down 20 or 200 fathoms, or more, does not signify, so "H. K." says, although I have myself seen an iron nun buoy collapse when a ship's anchor has been let go in deep water with too short a buoy rope; but we will allow "H. K." to make his own buoys, and grant that they will stand the pressure at the depth.

The cable ships separate, and the cable is paid out; a breeze springs up (which, sooner or later, it will), and on the second day, when it is time to lay another buoy, it is blowing strong, with a good sea on. The sounding ship must sound; there can be no waiting for the weather this time; she rounds to for the purpose, but cannot keep head to sea; she heaves the sounding lead, fails, heaves again, loses lines, and at last signalizes that she *thinks* there is 2,000 fathoms; as to allowance for drift, surface current, &c., that is out of the question, and there is even doubt as to whether the sinker had reached the bottom at all. However, the buoy must be moored; the cable is bent on at, say, 1,800 fathoms, and mooring anchor gone—out it runs, and away goes buoy No. 2, when, if it is strong enough to bear the weight of its own cable, it may be seen dancing away on the top of the waves to windward; as to picking it up and shortening the cable, you might as well whistle for the buoy to go down the required depth. The cable ship may have been waiting for the sounding, most assuredly she would for mooring the buoy, during which time the cable *must* run out—light or heavy cable, it must go, the send of the sea and pitching of the ship will prevent any stoppage, except at the risk of the cable, and the ship may be miles from the spot where the sounding is taken before the anchor is at the bottom.

Now, Sir, I will ask any reasonable man if this is a matter of mere "adjustment," or any sailor if I have overstated the case. A real gale would finish the matter, and buoys, cable, and all would be lost. Thus, I think, I am quite warranted in saying the scheme is impracticable from "the insuperable difficulties attending laying the buoys," and that being the case, it is useless entering on such subjects as the nature of the buoys, cables for mooring them, accessibility of the telegraph cable for repair when laid, and many other serious and important questions, combining a great many etceteras not calculable by any rule of science or engineering—indeed, I believe it would be equally practicable to erect posts across the Atlantic, and thus have an atmospheric line, as to moor buoys for the purpose of supporting a submerged one.

I might safely leave the other objections to my arguments unanswered; but I repeat that at the bottom of the ocean there is no *superincumbent* pressure. As to the barnacles and weeds that "H. K." takes objection to, he has only to run down to Leith, obtain a handful of both from some ship's bottom, and throw them into the sea, when he will soon see if they will sink. And as to the question of the suitability of the bottom for the cable, I conceive my opinion, for the reasons given, is as good as any "H. K." can form on mere hypothesis.

Hoping this letter will satisfy "H. K." that his proposed mode of suspending submerged cables is impracticable,

I am, Sir, yours, &c.,
AN OLD SAILOR.

AN ATLANTIC TELEGRAPH.

SIR,—The statement made by Captain Selwyn, in your journal of 24th April, in support of the alleged existence of under-currents, particularly in the open ocean, is anything but conclusive. I may mention, with reference to what he says, that I have all due respect for eminent hydrographical authorities; but I am very far indeed from believing that they, or any other authorities, are infallible, nor do I suppose that the captain himself will contend that they are. When they assert anything to be true, the question remains open for the fullest and most searching discussion whether the facts bear out their assertion; and if it is not borne out, their authority, it is quite clear, ought then to go for nothing; although it has too often the very bad effect of imparting stability to error of greater or less duration, and more or less obstructive of the course of improvement.

I regret I have not seen Sir Edward Belcher's letter, referred to by the captain. But if its facts, or alleged facts, are of the same kind, and if its arguments are no better, than those of Captain Maury in his Chapter on Currents, it is a matter of very little moment. But the Admiral, in his own evidence, annexed to the Report on Submarine Cables, states a fact (page 245, question 4,298), the plain conclusion to be drawn from which seems to me to be most hostile to the existence of under-currents.

Captain Selwyn himself admits the singularly instructive fact stated by Commander Dayman, and quoted in my letter in your journal of 10th April. The captain says that he never knew another instance of the kind. But he must bear in mind that the Commander says that this occurred *twice*, and that during the comparatively short time in which he made soundings in the North Atlantic. Such an occurrence showed that there must have been complete stillness in the air, and in the water on the surface of the ocean, and all the way down to the bottom. Now stillness in the air, and in the water on the surface of the ocean, cannot, in the nature of things, be expected to occur often together; but, when they do occur, the result is as stated by the Commander, leading to the clear conclusion that there are no under-currents in the North Atlantic, nor, it may be further deduced, anywhere else in the open ocean. Those who assert the contrary must prove it.

The Captain says that boats, and even ships, have been carried forward at a considerable rate against surface currents by sinking an iron pot or other heavy body, exposing a large surface, 100 or 200 fathoms deep, so as to be acted on by the stronger under-currents. But Captain Maury's book contains one, and only one, alleged case of the kind, said to have occurred no less than 200 years ago in the Baltic. Captain Maury also quotes an apocryphal statement about what is alleged to have happened to a Dutch ship in the Gut of Gibraltar about 150 years ago—the statement also asserting that the Gut was very deep, and could not be sounded by the longest lines, which assertion is now known to be altogether untrue. The two stories bear all the marks of being untrustworthy; they have never been reverified in any way, though of such very ancient date; and, in short, according to all the recognized rules of judging of evidence, are not entitled to any credit whatever. Captain Maury also relates what was done by Lieutenants Walsh and Lee, U.S.N., by means of a block of wood loaded and sunk so far into the ocean after being tied to a floating barrel, when they allege the barrel made progress at the rate of 1 or 1¾ knots per hour against tide, wind, and surface current. But the time and place when and where this occurred is not specified. And the great question arises in this as in all similar cases, Was it the boat or the barrel that moved? The answer to which must be, in all probability, it was the *boat*, acted on by the tide, wind, and surface current, which are expressly admitted to have existed and operated together at the time of the experiment. And it is on these three small, miserable, most unsatisfactory, most inconclusive evidences of a direct kind that Captain Maury raises his huge system of under-currents, and on which Captain Selwyn rests his belief in its truth.

And what do they say is the cause of the alleged under-currents? Capt. Maury thinks they may arise from the difference in the specific gravity of the waters of the ocean—such consequences from such a cause being the pure offspring of his own imagination. Capt. Selwyn thinks that surface currents probably cause reciprocal under-currents; but why or how they should do so he does not say, and it is evident, from the use of the word "probably," that he does not know—that it is, in short, the mere offspring of his own imagination also. But the children of imagination, to whom facts are hostile, must speedily perish. The Captain, no doubt, refers to the Gut of Gibraltar as being a familiar instance of this reciprocal motion. But where is the proof of any such motion existing in the Gut? Does he refer to the old apocryphal story of the Dutch ship already alluded to?

Commander Dayman believes, and is fully justified in believing, from the soundings made by him above referred to, that there are no under-currents in the north part of the North Atlantic (Report, p. 385, q. 3211-2). Now this is the very place where the proposed surface cable would be laid. The absence of under-currents there, therefore, is all that I need really care about, and is all that is necessary for the present purpose. But still I may add that, if under-currents do not exist in that region of the ocean, why should they exist in any other region? The alleged facts, which are supposed by Captains Maury and Selwyn to cause under-currents, should exist and operate in the north part of the North Atlantic just as well as anywhere else. And since these alleged causes are found not to operate in the production of under-currents in the North Atlantic, why should we believe that they opereate to produce them anywhere else? And with reference to Commander Dayman's conclusions, I beg leave, with all due respect, to inform Captain Selwyn that I must attribute vastly more weight to such conclusions, deduced from actual observed facts, by a man so thoroughly and practically experienced in the matter as the Commander, than to the groundless suppositions and the imaginative speculations of Captain Maury and of himself.

No doubt, Captain Selwyn says, that on numberless occasions, after a regular descent, at gradually increasing intervals, he has seen and known the sounding line to be gradually increased in velocity of descent by the effects of an under-current. But the Captain here begs the whole question by saying that the acceleration was caused by an under-current. That is the very point in issue, and must not be assumed. I have seen, in the lowering of a bucket from a windlass down to the water in a well, the same sudden acceleration occur. Aqueous under-currents, as the cause in such a case, is out of the question. If Captain Selwyn had not been misled by the notion of these supposed under-currents in the ocean, and had sought the true cause of the accelerated motion in something else, he would no doubt have found it; for it is fully believed that it will admit of a very simple explanation, irrespective of under-currents altogether. To show a similar case of erroneous conclusion, drawn from the very same fact of acceleration in sinking, by a person having a predominant idea in his mind different from that in Captain Selwyn's, I would refer to Mr. Newall's evidence annexed to the Report on Submarine Cables, p. 252, q. 4419.

In short, the proof, such as it is, in support of the existence of under-currents in the ocean, fails entirely on every point. The belief in their existence, no doubt, originally sprang from under-currents existing in the atmosphere; but there is far too great a difference between thin gaseous air and dense liquid water—there is so great a difference in their mobility—that it will not do to argue that because under-currents exist in the one, they must exist in the other also. In truth, Captains Maury and Selwyn, by a strange inconsistency, admit this so far, because they both grant that under-currents do not exist at the bottom of the ocean,—but why, consistently with their views, Captain Selwyn has not explained, though I requested him to do so.

To make the matter on this point still clearer, indeed it may be said absolutely clear, it may be remarked that we know that it is the solar heat that sets the atmosphere in motion in horizontal under-currents and otherwise. This is accomplished by the solar heat easily penetrating through the thin air of the atmosphere down to the surface of the earth, which it warms, and where it thus accumulates, and then powerfully reacts upon the atmosphere, setting it in motion and giving rise to currents. But it is altogether different with the dense water of the ocean, through which the solar heat can only penetrate a very few feet down; and from the known action of heat on water, can in these circumstances give rise to no current motion, but only to evaporation. The distribution of heat throughout the ocean, and its effects, are also well known, and are equally conclusive against the alleged under-currents in the ocean. These two reasons ought of themselves to be perfectly sufficient to prove that no oceanic under-currents exists; but when they are coupled with all the other facts and arguments adduced in disproof of such currents, they ought, it is submitted, to be perfectly irresistible to every truly scientific mind.

But Captain Selwyn, in support of his views as to under-currents, draws farther upon the imagination, and holds that such currents must exist, because in his opinion "they are necessary to carry material to oceanic animalcular life to construct their shells." This notion is also promulgated by Captain Maury; who also contends that the Red Sea and Mediterranean would have been choked up with salt, especially the former, did under-currents not flow out of them—though such under-currents, it must be remarked, have never been seen by anybody, and for the existence of which, it may most safely be said, there is not a particle of truly scientific proof. And it may also be further remarked that nature attains her ends by much easier, simpler, and less cumbrous means than men in general are at first able to appreciate; and that the chemical doctrines of *solution* and *diffusion* afford sufficient insight into a much simpler, a more beautiful, a more efficient means of attaining the ends above-mentioned, so far as necessary, than would a system of under-currents, so cumbrous, and also so wasteful of power as to be impossible; for it may well be asked, Where could the requisite supply of power possibly come from? How could it possibly be generated?

Captain Selwyn alludes, in the course of his remarks, to what he calls the law of motion in water. It is evidently surface motion—waves and currents—caused mainly by currents of air, though also to some extent by the tides, to which he refers. Now the motion of the waves, most formidable looking as it often is, extends after all only a very few feet below the surface. The currents are regulated by the length of time, and the strength with which the wind blows in one direction. In the open ocean the tides produce no currents. The currents in the north part of the North Atlantic, where the Atlantic Cable would be laid, reach only a very few feet below the surface, if, indeed, they ever extend much more anywhere, except, perhaps, in one or two cases.

Captain Selwyn says that if I admit the existence of surface currents, and deny the existence of under-currents, why should I leave the tranquil depths below and take the cable into the troubled waters above? My reply is, that I do not propose to take the cable into the troubled waters above. The troubled waters in the open ocean, as already said, and particularly in the north part of the North Atlantic, extend only a few feet downwards—no further, there is every ground for believing, than 30 or 40 ft.—and, below that, the water is, and the cable and the buoys would be, perfectly still and tranquil; while there would be extremely little pressure on the cable and buoys nature of the bottom would be a matter of no moment whatever; and the cable would be accessible;—all ensuring the success of ocean telegraphy—a success not to be obtained by bottom telegraphy, with its most enormous and constant pressure; the certain unsuitability of the bottom in many places; and the utter inaccessibility of the cable: these immense disadvantages being sure to end in complete failure.

It may be observed that the truth of these views, as to the stillness of the ocean, may so far be very easily put to the test, by direct examination, by means of a diving bell sunk 30 ft. or 40 ft., or farther, below the surface.

It may also be observed that there is much to be done in the way of improving oceanic hydrography in other respects. Many of the views generally entertained in the present day with regard to the Gulf Stream, its course and effects, will yet be regarded with some degree of astonishment.

Edinburgh, May 11, 1863. H. K.

SPRING LOAD FOR SAFETY VALVES.

Sir,—Can you or any of your thousands of my fellow-subscribers give any good reasons why the spring load for safety valves, as used on locomotives, is not adopted in our steam marine, in lieu of the mass of weights which is the present practice? It is difficult to see why a mass of weights dangling inside or outside a boiler is to be preferred to the equally safe and much lighter spring. For, while the pressure of the spring is practically constant, the pressure of the weights, owing, of course, to the vertical action of gravity, is subject to constant and great variations through the working of the ship in a seaway, and these variations are greatest at the very time when steadiness is most required, viz., in bad weather, causing priming and all its attendant evils, of want of water, extra work for the feed-pump or injector, and these too at a time when they, especially the injector, will not work well, being greatly influenced by the same cause; nor must we omit the power of the weights in the ever-varying motions of a ship at sea to destroy the fit of the valve on its seat, causing a loss of steam which, towards the termination of a long voyage, is often considerable. It is well known that in bad weather the boiler is a source of great anxiety to the engineer, often through failure of steadiness causing the loss of a valuable ship and of still more valuable lives. Knowing that any suggestion tending to mitigate these evils will find a corner in your Magazine, I have ventured to address you, wishing to contribute my mite towards getting rid of, to my mind, a monstrous mechanical barbarity.

I remain, &c.,

Millwall, E. Robert Shenton.

Meetings for the Week.

Mon.—*United Service Inst.*—"Steering and Manœuvring Ships with Broadside Batteries by means of Twin Screw Propellers," at 8.30 p.m.

British Architects.—At 8 p.m.

Tues.—*Inst. Civil Engineers.*—I. Discussion upon Mr. Watson's Paper "On the Communication between London and Dublin." II. "On the Manufacture of Duplicate Machines and Engines," by John Fernie, Esq., at 8 p.m.

Royal Inst.—"On Sound," by Prof. Tyndall, at 3 p.m.

Wed.—*Soc. of Arts.*—"On Destructive Distillation, considered in reference to Modern Industrial Arts," by B. H. Paul, Esq., at 8 p.m.

Geological Soc.—I. "Further Observations on the Devonian Plants of Maine, Gaspé, &c.," by Dr. J. W. Dawson. II. "Notice of a new Species of *Dendrerpeton*, &c.," by Dr. J. W. Dawson. III. "On the Upper Old Red Sandstone and Devonian Rocks," by J. W. Salter, Esq. IV. "On the Relations of the Sandstone of Cromarty with Reptilian Footprints," by Dr. G. Gordon and the Rev. J. M. Joass (communicated by Sir R. I. Murchison), at 8 p.m.

Thurs.—*Royal Inst.*—"On Geology," by Prof. Ansted, at 3 p.m.

Antiquaries.—Ballot for the Election of Fellows.

Royal Soc.—At 8.30 p.m.

Chemical.—At 8 p.m.

Fri. — *United Service Inst.*—"The History of the Bayonet," by Capt. Sir S. Scott, at 3 p.m.

Royal Inst.—"On the Sun's Chemical Action," by Prof. H. E. Roscoe, at 8 p.m.

London Inst. —"On Economic Botany," by R. Bentley, Esq., at 7 p.m.

Architectural Assoc.—Class of Design—Metal Finial and Cresting.

Sat. — *Royal Inst.*—"On the Science of Language," by Professor Max Müller, at 3 p.m.

Miscellanea.

Improvements in Railways.—A new economic permanent way, designed by Mr. G. F. Griffin, is attracting attention. The sleepers are made of corrugated cast iron, and the cost per mile is stated at £1,245 against £1,806, or £1,844 under the existing systems. Apart from saving in annual maintenance, Messrs. Brassey, Betts, Trevethick, and others have given very favourable opinions of its qualities, and an experimental portion laid down about fifteen months ago on the Great Northern line is stated to have shown most satisfactory results.

In consequence of the great success which has attended the newly-invented ventilating arrangements on board the iron-clad screw frigate "Royal Oak," 35, Capt. Campbell, fitting for sea at Chatham, the Lords of the Admiralty have decided on introducing a similar system on board the other vessels composing the squadron of armour-plated steamers. Orders have accordingly been received at Chatham dockyard for one of the officials from Devonport dockyard to proceed to Chatham for the purpose of obtaining a knowledge of what has been done, with a view to their being applied to the armour-plated frigate "Ocean," recently launched at Devonport. The system of ventilation carried out in the "Royal Oak" is from a plan submitted to the Admiralty by Capt. Fanshawe, superintendent of Chatham dockyard; the engine-room and stoke-holes being ventilated according to the principles laid down by Mr. Baker, inspector of machinery, and the chief of the engineering department at Chatham.

A newly-invented electro-metallic coating is about to be applied to the plates of the iron-cased steam frigates "Gloire" and "Invincible." It appears that this new composition has been found to be very successful in the preservation of metals. The Minister of Marine has addressed a despatch to the several Port-Admirals instructing them to send a number of shipwrights to Paris to be instructed in the preparation of this new composition. Experiments likewise are about to be made to prevent the rolling of iron-cased ships.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 2805.
Boilers and Furnaces, 2808.
Ships and Boats, including their fittings, 2800, 2839, 2841.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 2809, 2821, 2825, 2847.
Cultivation of the Soil, including agricultural implements and machines, 2803, 2832, 2843.
Food and Beverages, including apparatus for preparing food for men and animals, 2826.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 2810, 2814, 2823, 2824, 2828, 2834, 2844, 2849.
Buildings and Building Materials, 2811, 2829, 2837.
Lighting, Heating, and Ventilating, 2802, 2830, 2842, 2846.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 2812, 2822, 2827, 2836, 2840, 2848.
Metals, including apparatus for their manufacture, 2807, 2813, 2831.
Chemistry and Photography, 2820.
Electrical Apparatus, 2845.
Warfare, 2819.
Letter-Press Printing—*none.*
Miscellaneous, 2799, 2801, 2804, 2806, 2815, 2816, 2817, 2818, 2833, 2835, 2838, 2850.

2799. J. and J. Cash. *An improvement in the manufacture of valentines.* Dated October 16, 1862.

This invention consists in manufacturing valentines in silk, or in a combination of silk and cotton, of the various colours required, according to the design or pattern to be produced, in an ordinary ribbon loom. Heretofore valentines have been generally made of paper, and in all cases the design or pattern has been produced by colours applied by printing or by the brush; now highly illuminated valentines will be produced by this invention with the colours for the necessary design woven into and forming part of the fabric composing the valentine. *Patent abandoned.*

2800. J. Robinson. *Improvements in protecting the sub-*

merged portion of iron ships, and in ventilating the cabin and cabin decks in iron ships. Dated October 16, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2801. E. Stely, jun. *Improvements in envelopes.* Dated October 16, 1862.

In carrying out these improvements, the inventor takes any ordinary blank or pattern of envelope having side flaps or lappets, and the top or seal flap and the bottom or pocket flap each so shaped that there is no one flap or folding piece of the same size or shape as the envelope face. He folds and gums the blank in the ordinary way, and along the upper edge of each of the side flaps or lappets, and inside thereof, he lays on a thin slip of gum; he then introduces the second piece of plain or coloured paper, or other material, so as to form a square pocket, this second piece being secured to the under face of the side lappets and the upper point or tongue of the bottom or pocket flap. *Patent abandoned.*

2802. E. Nelson. *Improvements in the manufacture of apparatus for heating and superheating steam and air without decomposition.* Dated October 16, 1862.

This invention consists, principally, in the use of highly refractory materials in such manner as to prevent decomposition, and render the apparatus perfectly air and steam tight. *Patent completed.*

2803. J. Summerton. *Certain improvements in harrows for harrowing land.* Dated October 17, 1862.

This invention consists in forming the principal parts making the harrow or implement of a triangular radial shape, which, by preference, the patentee forms from cast iron, the same having flukes or projections on both sides, the points of which curve forward in the direction of the line of draught, and are larger on one side than the other. These angular pieces are connected by links or rings in the order as to equally distribute the effect of the flukes or projections as the harrow passes over the surface of the ground in the process or operation of harrowing. *Patent completed.*

2804. H. Wickens. *Improvements in machinery for making nails.* (A communication.) Dated October 17, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2805. J. and G. Davies. *Improvements in rotary engines, rotary pumps, and rotary blowing machines.* Dated October 17, 1862.

This invention consists—1, in guiding the sliding pistons by means of projections on their inner ends engaging in grooves in the end plates of the fixed cylinder, against the inner sides of which grooves the said projections bear. As the small cylinder rotates, the sliding pistons are pressed outwards, and made to bear accurately against the fixed cylinder by the inner sides of the grooves acting on the projections on the inner ends of the sliding pistons. The inner or guiding surfaces of the said grooves are nearly, but not quite, circular, being of greatest radius in a plane parallel to that of the spring bearing. Instead of the grooves described, fixed irregular cams on the plates closing the fixed cylinder may be used with like effect. 2. The invention consists in the employment of a self-adjusting packing on that edge of each sliding piston which bears against the fixed cylinder. *Patent completed.*

2806. W. S. Kennedy. *An improved method of, and apparatus for, applying fomentations and other external remedies to the throat.* Dated October 17, 1862.

An extension of time for filing the final specification of this invention having been petitioned for, the documents relating thereto cannot at present be seen.

2807. G. T. Bousfield. *Improvements in the manufacture of iron and steel.* (A communication.) Dated October 17, 1863.

In the manufacture of iron and steel by blowing atmospheric air into and through melted cast iron when contained in a suitable vessel, it has been usual to employ several tuyeres at or near the bottom of the vessel containing the melted cast iron. This invention consists in applying a single tuyere at the side of the vessel near the bottom. The form of the tuyere may be varied. By thus using only one tuyere, considerable advantage is derived in this manufacture. *Patent abandoned.*

2808. J. H. Johnson. *Improvements in the prevention or removal of incrustations in or from steam generators.* (A communication.) Dated October 17, 1862.

This invention relates to the use of certain additional ingredients in the manufacture or preparation of the peculiar liquid for preventing and removing incrustation in or from steam generators, for which letters patent for the United Kingdom were granted to the present patentee on the 25th day of January, 1862, (No. 196), and consists in the addition to the ingredients named in the specification of the patent above referred to of one part by weight of tan or powdered oak bark converted to an extract, and reduced to 12 deg. Beaumé, five parts by weight of natural leaves cut into shreds or small fragments, and two parts by weight of animal marrow. The following are the ingredients and proportions now proposed to be employed, and which have given the best results, although the proportions may be varied slightly:—Snail or snug liquor, one hundred parts by weight; carbonate of potash, eight parts by weight; molasses or treacle, two parts by weight; leaves of the aloe, five parts by weight; animal marrow, two parts by weight; extract of tan, 12 Beaumé, one part by weight. These ingredients must be boiled together for about two hours, and then strained off, when the liquor will be ready for use. *Patent completed.*

2809. R. Webster. *Improvements in means or apparatus for preventing or mitigating accidents arising from collisions of railway trains.* Dated October 18, 1862.

This invention consists in the application to each end of railway trains of a fender or projecting guide frame, which is formed with an incline or slope, or at an angle to the rails, in such manner that when two trains come in collision the said fenders or guides of each train will come in contact with each other, and the inclines thereof will cause the trains to be deflected, or guided sideway from the rails, so as to pass each other, and thus avoid direct concussion, which is now the case when two trains come in collision. *Patent abandoned.*

2810. E. Lord. *Certain improvements in machinery for opening and cleansing cotton and other fibrous substances.* Dated October 18, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2811. H. Ledger and B. Williamson. *An improved substitute for tombstones, tablets, monuments, and other similar memorials or commemorative records.* Dated October 18, 1862.

This invention relates to a substitute for tombstones, monuments, tablets, and other similar memorials, and consists in a combination of metal and glass, or other vitreous substance, the body of the record or memorial being constructed of cast or wrought metal, and arranged so as to receive panels of glass bearing an inscription, or lettering, or ornamental designs. These panels are to be secured from the inside, and packed and bedded in any cement, and so arranged that they may be taken out for additional lettering if required. The lettering may be preserved by varnishing or painting the back, and the metallic portion of the structure may be painted in representation of stone, marble, or otherwise, the whole forming a durable and economical substitute for the materials ordinarily employed in such records. The patentees further propose that wood, stone, marble, porcelain, cement, or any plastic materials, may also be employed with glass for such purposes. *Patent completed.*

2812. J. Bentley. *Improvements in apparatus for forming and pressing felt hats.* Dated October 18, 1862.

This invention relates to the apparatus ordinarily used for forming and pressing felt hats, and consists in certain various alterations in the form and arrangement of the said apparatus, and also in certain additions thereto. The first improvement consists in forming the lid or cover of the apparatus with a hinge or joint, on which it turns when lifted off the other part of the apparatus. The second improvement consists in forming the pin of the hinge with a passage through it, which communicates with another tube or passage formed in an arm connected with the lid, and forming part of the hinge. Through these passages the water is supplied to the interior of the apparatus, or discharged from it at pleasure. The third improvement consists in the mode of applying the india-rubber or elastic bag. This the patentee attaches to the under side of the cover by means of a hoop or ring, which is secured to the cover by means of screws. The fourth improvement consists in the mode of securing the cover or lid to the body of the apparatus. This he effects by means of radial bolts, which are acted on by a cam turning on a centre at the middle of the outside of the cover. The fifth improvement consists in forming the basin or mould in two or more separate parts, and at the same time firmly securing the parts together when in use. The sixth improvement consists in the application of a gauge of a peculiar construction for indicating the pressure of the water when the apparatus is in use. This gauge is placed in a conspicuous position, so that the operator can at all times know at what pressure he is working. *Patent completed.*

2813. B. Lauth. *Improvements in machinery or apparatus for polishing sheet iron or other metal.* Dated October 18, 1862.

In carrying this invention into effect the patentee employs three or more rolls, mounted on a suitable frame, and placed one above the other, their axles being horizontal and parallel to each other. He prefers the use of three rolls only, the upper and lower rolls being of equal diameters, and the other or intermediate roll, which works in contact with the other two, being of a smaller diameter. The sheet iron or other metal to be polished is to be passed (either one or more sheets at a time) between these rolls, and their operation will polish the sheets and give them a beautiful lustre. By the employment of three rolls of different diameters arranged in the aforesaid manner, a sufficient pressure can be obtained to lengthen or draw the thinnest sheet iron or other metal, which has been hitherto unattainable by the application of rolls arranged in any other way. By passing two or more sheets at a time through the rolls, the pressure will be augmented, and the amount of work performed will also be proportionally increased. *Patent completed.*

2814. R. A. Brooman. *Improvements in frames for doubling and twisting threads.* (A communication.) Dated October 18, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2815. J. Fuller. *An improvement in treating india rubber used on a wire or wires for insulating the same.* Dated October 18, 1862.

This invention consists in treating india rubber after it has been placed on a wire or wires to insulate the same for electric telegraph purposes by first applying thereon naptha or other solvent water, or other matter that will render the surface of the rubber covering damp or adhesive, then powdering or otherwise applying sulphur, and exposing the rubber so treated to heat in order to "cure" the same. Or before the curing, more india rubber may be applied on the sulphured india rubber, and the "curing" may be effected after the additional india rubber has been applied. *Patent completed.*

2316. W. E. Gedge. *Improved apparatus for extracting condensed steam.* (A communication). Dated October 18, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2817. W. Clark. *Improvements in apparatus for dredging.* (A communication). Dated October 18, 1862.

The object of this invention is to render streams, rivers, or other channels navigable at all times, which otherwise, by reason of the displacement or accumulation of the sand or mud caused by floods, have their channels blocked up by sand banks. The principal features of this invention are—1, That it is self-acting, being actuated by a hydraulic wheel driven by the current. This wheel communicates motion by means of suitable gearing to one or more screws used for raising the sand; and, further, the apparatus only works during the tide. 2, It is only necessary to be about 6 ft. high, and may be kept at the mouths of rivers during bad weather. 3, The various parts of which the apparatus is composed always retain their proper position, therefore the useful effect is always at the maximum. 4, The small size of the driving wheel renders it little liable to damage from the violence of the sea. *Patent completed.*

2818. J. Tangye. *Improvements in or addition to certain kinds of pulleys for raising heavy weights.* Dated October 20, 1862.

This invention relates to pulleys of the kind called differential pulleys—that is, pulleys of the kind described in the specification of letters patent granted to Thomas Aldridge Weston, dated the 25th day of April, 1859 (No. 1033), and consists in the mechanical arrangements hereinafter described, by the use of which the said differential pulleys may be applied to the lifting of heavier weights than they can conveniently be applied to the lifting of as ordinarily constructed. To the axis of the pulley the patentee attaches a toothed wheel, with which toothed wheel a pinion on another and parallel axis engages. The axis of the said pinion carries a ratchet lever or winch with which to turn it; or it is provided with a spocket wheel with an endless band passed over it for the same purpose. By giving a rotary motion to the axis of the pinion, a slow motion is given to the differential pulley. By this invention differential pulleys may be made very powerful, without increasing the size of the pulleys to an inconvenient extent. Although a train of one toothed wheel and a pinion is sufficient for all ordinary purposes, yet multiplying gear, consisting of a longer train of toothed wheels, may be employed where it is desirable. The toothed wheel and pinion may either work within or without the frame carrying the pulley. Where the pulley is small, the toothed wheel may be conveniently made hollow, the pinion taking into teeth on its inner surface. *Patent completed.*

2819. G. Haseltine. *Improvements in forging cannon and other heavy articles.* (A communication). Dated October 20, 1852.

The object of this invention is to make a cannon or other similar and analogous forging, by combining and welding rings or hoops in such a manner that the fibres of the metal will be continuous and concentric with the axis, and the welding of the rings together consolidates the entire mass, without exposing it to the action of the heat, except at the points where the welding is to be effected, and at the time only when it is necessary to heat those parts in preparation for their junction. *Patent completed.*

2820. R. A. Brooman. *Improvements in transferring designs and prints produced by photography to stone or zinc.* (A communication.) Dated October 20, 1862.

This invention consists in reproducing prints produced by photograpy upon lithographic stones, or upon zinc plates. Preference is given, however, to lithographic stones, and the inventor describes the invention as applied to such stones. He takes a lithographic stone and grains it, as for ordinary use. He places it flat upon a table, and throws over its surface a small quantity of a composition of water bichromatized to saturation, and of thick solution of gum arabic mixed in equal proportions, and spreads it equally over the surface of the stone, and rubs with a clean rag to dryness. He takes a transparent positive photograph upon glass, and applies it with the face carrying the impression in contact with the stone, and fixes down the corners of the glass with wax or cement. All this is performed in a dark chamber. In some cases, especially where photographs cannot be readily obtained upon glass, he uses positives on paper. The positive being fixed upon the stone is covered with a black cloth to protect it from light, the stone is then taken to the spot where it is to be exposed, and the cloth is removed. The light should be brilliant or diffused, according to the design on the photograph; brilliant for sharp lines, and diffused for designs possessing delicate half tints. The time of exposure will vary with the light—on a fine day at noon, for example, about one minute will suffice. After the time allowed has elapsed, he covers the stone with the black cloth, and returns it to the table in a dark chamber. He raises the glass or paper with care, and throws on the stone a solution of potass, for the purpose of destroying the coat of bichromatized gum in those parts protected from the action of light, and to form a slight engraving. In about a minute or more he inclines the stone and allows it to drain, then places it flat and passes over it a sponge containing some such fatty matter as soapsuds, which he causes to enter into the engraving produced by the solution of potass. He next wipes the surface with a soft linen or other rag, and when dry, he gums the stone as in the ordinary lithographic process after it has been acidulated. He leaves the stone to rest for about a quarter of an hour, and then inclining it, washes it with plenty of clear water, and allows it to drain. He again gums it and places it on a lithographic press, allows about a quarter of an hour or more to elapse, and then inks the stone and proceeds to print as in the ordinary process. *Patent abandoned.*

2821. J. Clark. *Improvements in the means of applying railway breaks.* Dated October 20, 1862.

This invention relates more particularly to continuous breaks, or that class of breaks in which the break-power is applied to any number of carriages in the same train, either simultaneously or in rapid succession. The patentee proposes to employ ordinary break-blocks of wood or metal suspended from the carriage frame, so as to clip or fit on to the peripheries of the running wheels, and to apply one or two blocks to each wheel, and on one or both sides of the carriage as may be desired. On the lower part of each of these blocks, he mounts a pulley grooved at the periphery to receive a rope or chain, which rope or chain, being passed over or under and round, and partially round the pulleys placed one before and the other behind the carriage wheel, will cause the said blocks, when the said chain or rope is tightened, to grip the said wheels and retard or counteract their rotary motion. Each carriage being fitted with these break blocks, the rope or chain passes along from one end of the train, encircling the pulley or pulleys of each block or blocks, to the other end of the train, where one end of the said chain is attached to, and wounded upon, a winding drum fitted to the engine, tender, or guard's van, as the case may be. This drum may be turned by hand if necessary by fitting suitable gearing thereto, but he proposes to mount it upon a shaft, sling levers (or in-sliding bearers), and on one or both ends of the drum shaft to fit a driving wheel or pulley, to be turned by being brought into contact with the periphery of the engine, tender, or carriage wheels, as the case may be, or into contact with the rails, so as to make the momentum of the train the power for actuating the breaks. The break-power may be thus applied from one or both ends of the train simultaneously. *Patent completed.*

2822. N. R. Hall and M. L. Parnell. *Improvements in the construction of thermometers.* Dated October 20, 1862.

This invention consists in stretching between two fixed pins or stationary points (which said pins or points can be fastened in a wall or elsewhere, or in a portable frame) a suitable length of wire, to which is connected a spring, and is so adjusted that the spring shall be drawn out or wound, which will keep the wire in a strained position; and the changes of temperature causing the wire to expand and contract, the spring will give or take by this arrangement, and form the working part of this thermometer. *Patent completed.*

2823. W. A. Turner and T. T. Coughin. *Improvements in apparatus for measuring cloths and other fabrics, parts of which are also applicable to indicating distances travelled by vehicles.* Dated October 20, 1862.

This apparatus consists of two upright ornamental standards formed by iron strengthened by tie rods. The upper parts of the standards contain bearings in which a metal or wooden roller is set, the axis of which is extended so as to be fitted with a crank handle, and with a small driving pulley. Another similar roller of different diameter is set in bearings working in slots and in the standards above the former roller, on which it rests; this latter is likewise fitted with a pulley, and is enabled to rise and fall in the slots according to the thickness of fabric to be passed between the two in course of measuring. The top of the standards supports a cross-bar, on the centre of which is fixed an indicator, consisting of a circular dial having numbers thereon, indicating yards or metres or other measures, and another series of numbers indicating tens of yards or metres up to any desired number. There are two hands or indicating pointers turning in the centre, one for each series of figures. Behind the dial a series of toothed wheels and pinions are set in bearings, actuating each other after the manner of clockwork, the first wheel receiving motion by means of a worm or endless screw, set on a shaft worked by a pulley at its extremity, the shaft extending from the indicator along the cross-bar, so that its pulley may be exactly vertical above the former pulleys described. Around the driving pulley and the uppermost pulley a vulcanized india-rubber band is to be stretched, so that the goods to be measured pass between the two rollers, turning the same; the indicator will be actuated and correctly register on the dial the quantity of fabric which has been drawn through the apparatus. The lower roller must be so arranged with regard to its circumference as to indicate yards on the dial, but the upper roller must be of such dimensions as to cause the dial to register metres or other required foreign measure; and when such foreign measures are required to be ascertained, the india-rubber band must be detached from the lower roller, and a shorter one, but crossed, may be adjusted so as to be stretched around the pulley of the upper roller and that of the indicator. In front of the apparatus, on the opposite arms of the standards to those which contain the foregoing portions of the machine, a shaft is set in bearings turned by a handle. Upon this shaft the goods may be wound or rolled up as they come through the measuring rollers. When the apparatus is not required to roll goods, but only to measure and examine them, the shaft and handle may be dispensed with, and the machine may only consist of the two rollers set in standards with the indicating apparatus; then, by by turning the handle of the measuring roller, the goods will be passed through the rolls, and may be examined and measured thereby, either for English or foreign measures. The lower portions of the standards serve to contain or support in bearing tightening or friction rollers, over and under which the fabric passes, and whereby a stress is laid upon it, so as to cause it to be tightly rolled up. *Patent completed.*

2824. J. B. Payne. *Improvements in machinery for pinning, twisting, and doubling and laying of hemp, flax, and other fibrous substance.* Dated October 20, 1862.

According to the first improvement the slivers wound on bobbins are placed in separate rotating frames or cages, called "sliver cages," in which are mounted drawing rollers, whereby the sliver is drawn down to the proper size. A proper drag or tension is put upon the sliver by means of a disc or plate, which is, by means of a spring, pressed down on the sliver, and produces a drag thereon as the bobbin is pulled round by the drawing rollers. The sliver cage is rotated at considerable speed by suitable driving gear, and thereby puts a twist into the drawn out sliver, motion being at the same time given to the drawing rollers by means of a screw shaft or other equivalent mechanism, which is by preference driven by a stationary toothed wheel, into which a pinion or one end of the screw shaft gears and works as the sliver cage is rotated. The drawn out sliver, after being twisted into a yarn, passes out of the sliver cage or frame through a central hollow spindle, and is conducted to another rotating apparatus, which the patentee calls a "tension rotating bobbin frame," by which an additional twist is put in the yarn while kept in a state of tension. This tension rotating bobbin frame is arranged to be driven in such manner that the drawn-out and twisted or spun sliver from the sliver cage will receive more or less twist, as may be desired, while under tension, and in this state the yarn will enter a rotating apparatus, which he calls a "hink preventor," and thence the yarn passes to a doubling or laying spindle, constructed according to the product desired, whether twine, line, or rope. The apparatus which he calls a "hink preventor" is, as above stated, placed between the rotating tension bobbin frame and the laying or doubling spindle, and by means of a series of grooved or other rollers holds the yarn so as to prevent twist passing the part held; thence by the rotation of this apparatus additional twist is put into the yarn intermediate between the "hink preventing" apparatus and the laying or doubling spindle, while twist is taken off the yarn intermediate between the apparatus and the "tension bobbin frame." *Patent completed.*

2825. H. L. Emery. *Improvements in endless chain railway horse powers.* Dated October 20, 1862.

This invention relates to that class of power machines in which force is generated by animals travelling on an endless platform, causing the latter to move in an opposite direction. The invention consists chiefly in a peculiar construction and arrangement of the shafts, gears, pulleys, and their fastenings, for the purpose of obtaining different degrees of force and motion without change in the speed or labour of the animals, in the manner of adjusting the tension of the endless platform to accommodate the run and wear of the latter, and in an improved form and combination of different parts to secure cheapness of construction, and economy and efficiency in working the machine. *Patent completed.*

2826. J. H. Johnson. *Improvements in apparatus for boiling liquids and cooking or preparing food; applicable also as a night-light.* Dated October 20, 1862.

According to this invention it is proposed to combine a vessel or receiver for the liquid to be boiled or heated with a lamp or gas jet or jets in such a manner as to allow the chimney of the lamp or gas flame to pass up the centre of the vessel, and be surrounded by the liquid contained therein. *Patent completed.*

2827. W. Butlin. *Improvements in machinery for splitting leather, and also for making usuable leather out of waste pieces, likewise the machinery necessary for the production of the same.* Dated October 21, 1862.

Provisional protection has not been granted for this invention.

2828. W. Tristram. *An improved method of preparing and dressing yarns or threads to be employed as warps.* Dated October 21, 1862.

This invention consists in a novel adaptation and combination of machinery to effect the desired object perfectly and expeditiously. The operation is conducted as follows:—The yarn is first to be bleached in the bundle, then wound, by means of swifts in the warping frame, on to warpers' bobbins, then from the bobbins on to the back beams in the beam warping mill, or employed for beam warping for taped or dressed work. Next, the inventor arranges any number of these back beams in one end of a dressing machine, called a "kreel," and runs the yarn through a weaver's reed on to a weaver's beam at the opposite end of the machine. For dressing the yarn, he employs a circular brush and hot cylinders or chambers in combination with the above-named machinery. *Patent abandoned.*

2829. W. H. Tucker. *Improvements in self-closing apparatus for doors.* Dated October 21, 1862.

This invention consists, primarily, of particular modes of applying weights to doors, so as to make such doors self-closing. To the seat of a frame or case, which the inventor conceals in the floor, or in a recess behind the doorpost, as occasion may require, he firmly fixes an upright screw shaft, having one or more long spiral threads around its circumference, to which shaft he attaches a moveable screw box or nut, so formed externally that it can be either directly or indirectly acted on by a piece connected with the door, so as to be caused to rise upon the shaft, and also formed so that a weight can be connected with or made to form a part of it, and rise with the nut as it is turned upward on the shaft by opening the door in either direction, and carry the nut downward, and, consequently, close the door by its pressure when the door is again released. *Patent abandoned.*

2830. J. Bryam. *Improvements in lamps for the combustion of paraffin, rock oil, or other oils.* Dated October 21, 1862.

This invention relates to the coneless or coverless-burner lamps, or those having no cover over the burners, and the improvements consist in constructing such lamps so as to to be able to regulate the flame or the quantity of light, as may be required, without having to take out the clams or wick holder to adjust the wick for that purpose, and thus avoid the danger of breakage of the glass chimney, or of igniting the oil in the lamp by such operation; also to prevent waste of oil or the surplus oil from the burners from running down outside the lamp. These improvements are effected by dispensing with the clams or wick holder, and by applying an adjusting spindle and pinions to propel the wick up or down the burner, and the inventor provides troughs to receive the surplus oil, and to conduct it back into the lamp. *Patent abandoned.*

2831. S. Whitham and T. Wright. *Improvements in the manufacture of iron and steel, and in the apparatus employed for that purpose.* Dated October 21, 1862.

The patentee claims the application of hollow lining plates to puddling ball and mill furnaces, in such manner as to form chambers around and underneath the hearth, and supplying the same with atmospheric air for the purpose of preserving the hearth from the action of the flame and liquid metal; 2, the means or method of heating atmospheric air and applying it to such furnaces, as described; 3, the application of a current or currents of water to the doors and frames of such furnaces for keeping them cool. *Patent completed.*

2832. C. G. Clarke, jun. *Improvements in garden shears.* Dated October 21, 1862.

The object of these improvements is to collect the cuttings produced in trimming the edges of lawns or grass borders with garden shears. For this purpose the patentee applies to the lower blade of the shears a receiver of metal, or other suitable material, and of form inclining outwards and upwards, so that, whilst it is capable of collecting the cuttings produced by the use of the shears, it may not interfere with their proper action, by which cleanliness, with economy of labour, will be effected. *Patent completed.*

2833. C. Clark. *Improvements in cigar tubes, and in cigar and pipe mouth-pieces.* Dated October 21, 1862.

This invention consists of a hollow mouth-piece, terminating in a small tube perforated longitudinally, pointed and barbed. In using this mouth-piece, the piercer or pointed end is inserted at the end of the cigar, or at the side if necessary. In hollowing the mouth-piece in which the tube or piercer is fixed, the inventor carries the opening of the tube which encircles the piercer, and into which opening the end of the cigar is intended to be partially inserted, of sufficient length from the point of the piercer inwards towards the mouth end, to leave an open space or cavity between the end of the cigar and the junction of the outer or cigar tube and the inner or piercer tube, to intercept the oil of the tobacco secreted by condensation when smoking; by thus making the tube inverted and double, the oil that is collected in the cavity cannot enter into the mouth, or escape until the entire cigar is consumed, or the end removed. To prevent the piercer tube from splitting the cigar, instead of making it terminate in a tapered tube or single piercer, he divides the tube, and points and barbs each half, so that it forms a double-pronged piercer. *Patent abandoned.*

2834. J. T. Cooke. *Improvements in battens for weaving.* Dated October 21, 1862.

This invention was described and illustrated at page 324 No. 227 of the present volume of this journal. *Patent completed.*

2835. R. A. Brooman. *Improvements in water-proofing, and in recovering products employed therein.* (A communication.) Dated October 21, 1862.

This invention consists in rendering materials more or less waterproof, and in recovering the volatile solvents used in the operation in manner hereafter described. The inventor dissolves caoutchouc, gutta percha, resins, or metallic soaps, in bi-sulphide of carbon, ether, or other like volatile solvents, and adds or not sulphur. By the term metallic soap he means that material which is obtained by combining metal dissolved in acid with the fatty matter of soap in solution. He places the solution of any one or more of the substances above-named in a vessel closed air-tight, or nearly so, and after immersing the materials therein he draws them through an air-tight channel into another vessel. He shuts off communication between the two vessels and applies to the second vessel heat, which he prefers to be that derived from hot water, steam, or hot air, to evaporate the bi-sulphide of carbon, or other volatile solvent used; the vapour is received in a pipe or coil, and is condensed by any of the ordinary methods of condensation. The solvent is gathered in its liquid state, and may be used over and over again. *Patent completed.*

2836. G. T. Bousfield. *Improvements in the manufacture of boots and shoes.* (A communication). Dated October 21, 1862.

The patentee claims a boot or shoe having a sole of india rubber secured thereto by means of nails or rivets embedded in the vulcanized rubber, as described. Also a sole of india rubber vulcanized around the heads of the nails, by which it is to be secured to the upper leather and inner sole, as described. He also claims the use of canvas or cloth in combination with the above sole of india rubber, the nails being passed through the canvas and the canvas secured to the rubber, as described. He also claims the mould in which the sole is vulcanized, having cavities or holes for the reception of the nails. *Patent completed.*

2837. J. Duke and J. Clever. *Improvements in the manufacture of cement.* Dated October 21, 1862.

For the purposes of this invention, the patentees first calcine white or blue lias limestone, mountain limestone, or other carbonate of lime, and having slaked the resulting lime they mix it with slate, clay, potters' clay, porcelain clay, fire clay, or other silicates of alumina, and they intimately combine these materials in a finely divided state in a wash mill, with sufficient water to hold them in suspension; the mixture is run into settling pits, and when it has settled the water is run off, and the residuum is dried and burnt until the silica combines with the lime; it is then ground fine, and is fit for use as cement. *Patent completed.*

2838. G. Haseltine. *Improvements in the mode of, and in machinery for, manufacturing nails, brads, and other similar articles.* (A communication). Dated October 21, 1862.

This invention consists in producing simultaneously two nail blanks, brads, or other similar articles by means of a single punch and die, thereby avoiding the necessity of reversing or shifting the plate after it is placed in the machine; in forming the die of two adjustable metal bars, the ends of which form the cutting edges, whereby a saving is effected in the expense; and in combining and arranging different parts to secure simplicity and efficiency, and, consequently, economy in constructing and working the machine. These improvements are more especially applicable to machines designed for manufacturing from plates of metal, the width of which is equal to the required length of the nail blanks or brads. *Patent completed.*

2839. F. Tolhausen. *An improved machine for raising, lowering, removing, and carrying buildings, monuments, and ships or vessels.* (A communication.) Dated October 21, 1862.

This machine consists of a skeleton frame or scaffolding built all round, and underneath the building, ship, or heavy body to be moved. The part of the said frame that is underneath is moveable, and the other part is stationary. The moveable part is fitted with a number of nuts, into which work screws that are driven by double or treble worm and wheel gear, so as to produce the power required for lifting the heavy body by means of the screws aforesaid. The said heavy body is then placed on rollers or castors to be removed to its final place of destination. *Patent abandoned.*

2840. C. Trees and F. C. Belhomme. *Improvements in hats, caps, bonnets, and other coverings for the head.* Dated October 21, 1862.

In carrying out this invention, the patentees form the hats and other like articles for the head of any suitable soft material, such as cloth, silk, plush, felt, stuff, and the like, suitable for the inside lining in combination with a portion of gutta percha, or any other substance of the same nature, or possessing similar properties. These substances—with or without any suitable elastic fabric in combination therewith, or applied thereto—are cut to the required shape or pattern, and placed over a block, and then subjected to the action of heat applied by rollers, irons, steam, cloths, or other suitable means, whereby the said substances are made to adhere together. The parts previously cut to the required shape are then stitched or otherwise secured together by any of the known means now in ordinary use, thus forming a body or foundation for the hat or other article, a little mellow proofing being used, in addition to the substances above mentioned, in such parts as may require it, to aid in giving and retaining the required form preparatory to the first covering operation, in which first covering they use sheet gutta percha, or other substance of a like nature, as before described. The hats, caps, bonnets, or other coverings for the head thus produced may be crumpled up without injury resulting therefrom, as they will, immediately after such crumpling, resume their original form. *Patent completed.*

2841. G. Clark. *Improvements in the construction, protection, and armament of ships, vessels, and floating batteries, some of which improvements are applicable to land batteries and forts.* Dated October 22, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

2842. J. Spence. *Improvements in non-conducting compositions for preventing the radiation or transmission of heat or cold, and in coating metallic and other surfaces therewith.* Dated October 22, 1862.

In the non-conducting compositions made according to this invention, the patentee takes argillaceous earth, and grinds it or beats it up and mixes it with water, so as to form a paste. He then mixes oil cake, fish, or train oil, cow hair, carbonaceous matter, and the other materials, as herein mentioned, or their equivalents, for giving consistency, character, or colour, according to the purpose for which the composition is required. The hair is incorporated, and the whole is mixed and compounded until it has obtained the requisite degree of density or consistency. *Patent completed.*

2843. C. Webster. *Improvements in self-acting fountains adapted for garden engines, fire-engines, and for raising and forcing water from mines, wells, and other places.* Dated October 22, 1862.

Provisional protection has not been granted for this invention.

2844. E. Fielding. *Improvements in the manufacture of healds, and in machinery employed therein.* Dated October 22, 1862.

In manufacturing these improved healds, the inventor makes use of heald yarn of the usual description, but the eye of the heald, instead of being formed by looping the yarn, is produced by means of two small rings of metal or other material, which are threaded on the doubled yarns, and placed at the requisite distance apart, so as to leave the eye between them. *Patent abandoned.*

2845. H. Wilde. *Improvements in electro-magnetic telegraphs.* Dated October 22, 1862.

This invention consists in improvements in the transmitting instruments described in the specifications of letters patent granted to the present inventor on the 8th day of April and on the 10th day of August, 1861, and numbered 858 and 1994, respectively. In the specifications of these patents transmitting instruments are shown and described where the armature of a magneto-electric machine is mechanically geared with a radial arm which travels beneath a series of finger keys, any one of which being depressed, arrests the motion of the radial arm, and also the motion of the armature with which it is mechanically connected. In the present improvement the axis on which the armature or armatures are fixed has two different motions given to it simultaneously, in a circular and lateral direction, which two motions are produced by two different forces acting simultaneously in different directions. *Patent abandoned.*

2846. H. H. and J. F. G. Kronischrœder. *Improvements in the manufacture of gas meters, and in the manufacture of sheet metal suitable for gas meters.* Dated October 22, 1862.

In constructing the measuring drum for a gas meter, it is formed of two concentric cylinders, and the annular space between them is divided into a series of similar measuring compartments by partitions formed as hereafter explained. It is preferred that the annular space should be divided into four measuring compartments, but this is not essential. Each partition from the point where it is connected with the inner cylinder proceeds outwards from it in a straight line, and in such a direction that, if prolonged, it would pass through a small portion of the inner cylinder. After proceeding in this direction for about two-thirds of the distance between the point where it starts from and the point in the outer cylinder, which the line if continued would intersect, the partition descends in a straight line until it joins the outer cylinder; this it does at a point near to where a line drawn from the point where the partition is connected to the inner cylinder, and at a tangent to it would cut the outer cylinder. The water line in the meter is somewhat below the upper part of the inner cylinder, and gas is admitted above the water line into the interior of the inner cylinder. There is a passage formed through the inner cylinder into each measuring compartment, and such openings are immediately below the points where the partitions join the inner cylinder. In the outer cylinder there is an outlet passage formed above each partition for the passage of the gas out of the compartments, when the lowest end of the compartment comes above the water line in the meter. Interior of the central cylinder there is applied or formed a float to support or buoy up the measuring drum, but to which separately no claim is made. By a course of experiments, the patentees have found that rolled tinned sheet metal composed of the alloy of copper and tin hereinafter described, is not so prejudicially acted on by gas and moisture as the metals heretofore used. The alloy consists as near as may be of about sixteen parts by weight of copper and one and three quarters of tin. *Patent completed.*

2847. E. W. Hughes. *Improvements in turn-tables and turn-bridges.* Dated October 22, 1862.

For the purposes of this invention, in constructing the fixed circular track on which a turn-table or a turn-bridge is supported and turns, it is formed with a hollow groove, and by preference of an elliptical cross section, which groove is between two circular ridges or rails suitable for the support of wheels, as hereafter mentioned. The under surface of the turn-table or turn-bridge is made with a similar circular groove. In the groove of the fixed circular track is placed a number of spheres, on which the groove of the under side of the turn-table or turn-bridge is supported. In the centre of the fixed circular track is a fixed upright axis, which passes through the centre of the nave or boss of the turn-table or turn-bridge. Small spheres are introduced between the upright axis and the hollow centre of the boss or nave of the turn-table or turn-bridge, and between the circular fixed rack and the turn-table or turn-bridge there is a circular frame, which also turns on the central fixed upright axis. This frame is composed of several radial rods or bars, fixed at their inner ends to a central boss or nave, and at their outer ends they pass through and are affixed in a circular ring, which is of somewhat less diameter than the inner ridge or rail before mentioned of the fixed circular track, and they extend beyond the outer circumference of the fixed circular track. There is one such radial bar or rod in the space between each two of the neighbouring spheres which support the turn-table or turn-bridge. On each of these radial rods or bars are two wheels—one to run on the inner circular ridge or rail, and the other to run on the outer circular ridge or rail of the circular track. These two wheels turn freely and independently of each other, and the circular frame between the fixed circular track and the turn-table or bridge is supported by them. On each of the radial rods or bars is a wheel which turns freely on the rod or bar, and is of a diameter equal to or nearly so with the space between each two neighbouring spheres, so as to touch one or both of the two spheres between which it is placed, and by which it will be turned in an opposite direction to that in which the sphere in contact with it turns when rolling in the groove in the fixed circular track. *Patent abandoned.*

2848. T. Fearn. *Improvements in the manufacture of rods, poles, tubes, and other forms employed in the construction of various articles of furniture and for other similar purposes.* Dated October 22, 1862.

This invention relates more particularly to the manufacture and ornamentation of rods, poles, and tubes, such as are required for cornice poles, for making bedsteads, couches, chairs, and other analogous uses; and it consists in taking a core or base of metal, wood, paper, or other suitable material, either in the form of a tube, or of a solid, and coiling carefully round such core or base a strip or riband of thin metal, such, for instance, as brass or gilding metal. The core or base may be japanned, enamelled, or otherwise decorated before it receives the coil or twist, in which case a portion of the surface of the core may be left exposed, or the core may be left rough, and the strip or riband may be ornamented with an embossed or engraved enrichment, and coiled closely upon the core or base, thus producing a very rich and elaborate appearance at a low cost. *Patent completed.*

2849. T. Greenwood. *Improvements in machinery for preparing to be spun flax, hemp, tow, silk, waste, China grass, and other fibrous substances.* Dated October 22, 1862.

The object of these improvements is to expedite the dressing operation without injury to the material being dressed. This the patentee proposes to effect by applying a variable speed to the comb sheet, and thereby increasing the speed and action of the combs as the dressing proceeds. *Patent completed.*

2850. V. Orlowski. *Improvements in motive power carriages.* Dated October 22, 1862.

This invention consists in certain arrangements of mechanism whereby carriages may be propelled on common roads by manual labour. The inventor proposes to attach to, and fix on the axle of, the driving wheels at the centre thereof a small toothed pinion, into which a longer toothed wheel is made to gear, and which latter wheel is mounted on an axle set in bearings upon a standard in front of the driving seat, the standard being bolted to the framework of the carriage; or he causes the driving axle to be worked by means of an endless chain in lieu of toothed gearing. A winch handle is attached to the axle of the driving toothed wheel, or the wheel over which the endless chain passes, by which means the driver actuates the main driving wheels, and thus causes them to rotate, and thereby propel the carriage. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated Jan. 14, 1863.

116. W. Pidding, Cole-street, Southwark, gentleman. Improvements in the soles and heels of boots and shoes, in stud nails, tips, and toe or other plates used therewith, and in placing and securing them.

Dated Feb. 14, 1863.

373. C. P. Carter, Kennington-hall, Kent, esquire. Improvements in pavements for roads, streets, or ways.

Dated Feb. 26, 1863.

540. A. Capello, currier, 4, Rue du Repentir, Marseilles. An improved method of, and apparatus for, glazing Morocco leather.

Dated March 9, 1863.

655. W. J. Clapp, Nantyglo Iron Works, Monmouth, and N. Coats, Serhowy Iron Works, Monmouth. Improved armour plates for vessels, turrets, targets, forts, and other structures in which armour plates are or may be used.

Dated March 24, 1863.

768. H. Cook, Sunderland-terrace, Westbourne-park, gentleman. Improvements in the arrangement and construction of apparatus for transmitting electric currents and signals for telegraphic purposes.

Dated March 27, 1863.

805. W. Clark, 53, Chancery-lane, engineer. Improvements in winding or copping frames. (A communication).

Dated March 30, 1863.

817. T. Barnes, Earl of Dundonald, 12, Queen's-gate, Hyde-park. Improvements in treating fats and fatty oils and volatile oils or essential oils.

Dated April 1, 1863.

839. W. Clark, 53, Chancery-lane, engineer. Improvements in preventing fermentation in alcoholic and other liquids while drawing them from their containing vessels, and in apparatus for the same. (A communication.)

Dated April 7, 1863.

875. J. Macintyre, Burslem, Stafford, manufacturer. Improvements in the manufacture of knobs and other articles in china and earthenware.

Dated April 9, 1863.

895. F. J. Risse, Carlisle, engineer. An improved haft or handle for holding tools or instruments of various sizes.

901. G. Ferrand, Wooley-bridge, Derby, tin plate worker. Certain improvements in apparatus for supplying oil or other liquid lubricant to frictional surfaces.

Dated April 13, 1863.

930. R. Newton, Leeds, machinist. Improvements in machinery for separating and straightening the fibres of silk waste and other fibrous substances.

Dated April 15, 1863.

945. T. Gray, Lower Mitcham, bleacher. Improvements in preparing and bleaching flax, hemp, and other vegetable fibres, by which a brilliant lustre is imparted to those substances, and the fibres are separated.

Dated April 20, 1863.

984. E. W. Hughes, 28, Great George-street, Westminster, civil engineer. Improvements in turn-tables, turn-bridges, and slips.

Dated April 21, 1863.

986. H. Raften, 5, Barr's-hill-terrace, Coventry, artist. An improved process of obtaining printing surfaces.

Dated April 22, 1863.

1006. G. B. Barber, Park-street Boiler Works, Red Bank, Manchester, boiler maker. Improvements in steam boilers and apparatus connected therewith.

Dated April 24, 1863.

1014. J. Cavanagh, 21, Parron-street, Paddington, Liverpool. An improvement in cricket bats.

1018. J. Sheppard, Canterbury, conveyancers' clerk. Improvements in steam engines.

1022. J. Cornes, Roden-villa, and J. C. Davis, Cranbrook-park, gentleman, Ilford. Improvements in lawn-mowing, rolling, and collecting machines.

1024. J. Thompson, Bilston, manufacturer. Improvements in machinery for punching metals.

1026. J. Hinks, Birmingham, and J. Newman, Birmingham, manufacturers. Improvements in the manufacture of buttons.

Dated April 25, 1863.

1028. C. Pooley, Manchester, cotton spinner. Improvements in certain parts of machinery for preparing and spinning cotton and other fibrous substances.

1030. S. Harrison, York-street, Sheffield, stereotyper, type-founder, printer, and newspaper proprietor. A new and improved mode of manufacturing type for letter-press printing.

1032. T. A. Weston, Birmingham, mechanical engineer, and C. Vivian, Birmingham, machinist. Improvements in pulleys, capstans, and other machines for raising weights and transmitting motive power.

1036. A. Poirrier and C. Chappat Fils, Paris, manufacturers. Improvements in the manufacture of blue and violet colouring matters suitable for dyeing and printing.

1038. C. Beyer, Gorton Foundry, Manchester, engineer. Improvements in safety valves. (A communication.)

1042. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in thrashing machines, part of which improvements are also applicable for hulling, decorticating, cleaning, and polishing grains and seeds. (A communication.)

Dated April 27, 1863.

1048. J. J. Robert, 112, Rue du Temple, Paris, manufacturer of spoons and forks. Improvements in the manufacture of spoons and forks.

1050. M. Valkenhuyzen, Paris, gentleman. A new castor for furniture.

1052. J. Jeffreys, Upper Norwood. Improvements in constructing surface condensers, and apparatus for heating and cooling fluids.

1054. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in twisting and doubling silk, and in frames employed therein. (A communication.)

1056. W. Hudson, Burnley, gentleman, and C. Catlow, overlooker. Improvements in looms for weaving.

1058. H. Beare, Newton Abbot, Devon, agricultural implement maker. Improvements in machines for thrashing out corn from its straw, part of which is applicable for combing the straw.

Dated April 28, 1863.

1060. J. and W. Marris, Great Grimsby. An improved machine for breaking loaf sugar.

1068. G. S. Macdonald, Meard's-street, Soho. Improvements in card cases.

1070. R. Butterworth, Failsworth, mechanic. Certain improvements in carding engines to be employed for carding cotton and other fibrous substances.

1072. G. E. Donisthorpe, Leeds. Improvements in apparatus used when getting coal and other minerals.

1074. S. S. Marling, Stanley-park, Gloucester, woollen cloth manufacturer. Improved machinery for scouring, washing, and cleansing woollen cloths and other fabrics.

Dated April 29, 1863.

1078. W. E. Gedge, 11, Wellington-street, Strand. An improved system of permanent advertisement. (A communication.)

1080. W. Rodger, 9, Shawfield-street, King's-road, Chelsea, Captain in the Royal Navy. Improvements in anchors.

1084. F. Holcroft, Manchester, engineer. Improvements in the construction of pyrometers.

1086. M. Henry, 84, Fleet-street, patent agent. Improvements in apparatus for manufacturing beton and artificial stone, pugging clay, and other similar purposes, and in the production of artificial stone, and artistic, ornamental, and decorative articles, works, and surfaces. (A communication.)

Dated April 30, 1863.

1088. A. H. Rémond, 4, Moorgate-street. An improved process for retaining the aroma of coffee and cocoa.

1092. C. P. Stewart, Atlas Works, Manchester, mechanical engineer, and J. Kershaw, Duke-street, Westminster, civil engineer. Improvements in engines, machinery, and apparatus for obtaining compressed air, and for applying the power thereof in propelling railway and other carriages.

1094. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in rotary engines. (A communication.)

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated April 29, 1863.

1076. E. Rowland, Manchester, engineer. Certain improvements in apparatus for weighing solid bodies and for measuring fluids, parts of which improvements are also also applicable to the opening and closing of dampers.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, May 12, 1863.

3489. F. B. Henderson. Watches and other timekeepers.

3489. F. Lorut. Double weft-forks.

7. J. J. Southgate. Fire escapes.

11. J. B. Baker and J. Landon.. Boots, shoes, and other coverings for the feet.

12. W. A. Distin. Pipes.

20. J. E. Downson. Wrought metal piles, columns, and shafts.

21. R. C. Ransome. Reaping machines. (A communication.)

25. W. Philippi. Bearings and axle-boxes for machinery, carriages, and railway rolling stock.

39. D. Nevin and W. Coppin. Clearing and separating the woody parts from the fibrous portion of flax, hemp, or other like material.

44. J. Leigh. Treatment of gas.

47. M. Hodgart. Presses for pressing cotton and other substances. (A communication.)

50. G. Turner. Making leather from waste pieces of common leather.

53. J. Neale. Manufacture of capsules. (A communication.)

59. G. C. Grimes. Apparatus for treating splints.

60. G. A. Huddart. Buttons.

62. G. Dowler. Match boxes.

65. J. H. Johnson. Permanent way of railways. (A communication.)

69. C. Allen. Signalling on railways by detonating or explosive signals.

72. C. Worssam. Lithographic press.

90. F. Fenton. Manufacture of pulp for paper-making and similar purposes.

95. W. Clark. Winding or copping frames. (A communication.)

96. W. Clark. Carding engines. (A communication.)

107. R. A. Brooman. Machinery for lifting bobbins off spindles in spinning machines and in lubricating spindles. (A communication.)

142. D. F. Leblanc. A dioptical metallic level indicator or liquid gauge. (A communication.)

201. W. Clark. Piston valves and other pistons. (A communication.)

226. W. F. Stanley. Mathematical drawing instruments.

250. C. Mace. Steam engines.

276. F. G. Stuber. Air-tight boxes, cases, cupboards, and similar vessels.

535. H. Edmonds. Ventilation of ships and vessels, and apparatus connected therewith.

567. J. Maxfield. Brewing, and in apparatus employed therein.

720. W. C. Wild and J. H. Randel. Inlaying gold and other metals in glass, and in a composition suitable for the manufacture of jewellery and other ornaments, buttons, and other similar articles.

741. G. H. Smith. Sewing machines.

776. J. White. Removal of foulness of ships' bottoms.

785. R. A. Brooman. Manufacture of cords, ropes, and cables, and in machinery employed therein. (A communication.)

833. J. M. Dunlop. Ginning cotton.

886. T. Gray. Preparing and bleaching jute and other vegetable fibres for spinning and other purposes.

914. H. Caudwell. Construction of vessels of war, part of which improvements is applicable to fortifications.

930. R. Newton. Separating and straightening the fibres of silk waste and other fibrous substances.

945. T. Gray. Preparing and bleaching flax, hemp, and other vegetable fibres.

954. J. B. Watts. Steel sword hilts.

984. E. W. Hughes. Turn-tables, turn-bridges, and slips.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed May 8, 1863.

3017. G. H. Ogston.
3019. W. Simpson.
3027. J. B. Lavoine.
3037. W. Booth, J. Booth, and T. Booth.
3038. W. Palliser.
3039. H. Burridge.
3040. J. J. Parkes.
3041. E. Marriott and S. Holroyd.
3045. W. Dobson.
3048. F. J. Clowes.
3053. A. Twaddell.
3057. J. Slack.
3058. M. Defries.
3063. R. A. Brooman.
3082. J. Wilson.
313. G. Haseltine.

Sealed May 12, 1863.

3068. W. H. Andrew.
3077. A. and H. Illingworth.
3081. W. H. James.
3083. G. Gray.
3084. F. Palmer.
3089. W. Williamson.
3110. C., G., W., and J. Kilner.
3117. G. W. Oldham.
3124. W. Bottomley.
3136. J. Taylor.
3145. W. Clark.
3147. J. Webster.
3150. W. Clark.
3168. T. Fletcher.
3216. J. Irwin.
3249. H. Swan.

The *Morning Post*, of September 29th, when describing Benson's Great Clock in the Exhibition says: "The large clock in the centre transept, is a fine piece of mechanism, one of the largest chiming." Benson's new show-rooms contain clocks designed by the first artists of the day, and include clocks for the drawing-room, dining-room, bed-room, library, hall, staircase, bracket, carriage, church, turret, railways, warehouse, counting house, with musical, astronomical, and every description of clocks, from the plainest to the highest quality, of which the art is at present capable. Church and turret clocks specially estimated for. Benson's Illustrated Pamphlet on Clocks and Watches (free by post for two stamps) contains a short history of watchmaking, with descriptions and prices. It acts as a guide in the purchase of a clock or watch, and enables those who live in Scotland, Ireland, Wales, the Colonies, India, or any part of the world, to select a clock. J. W. Benson received a Prize Medal and honourable mention.—33 and 34, Ludgate-hill, London.—Established 1749.—[Advertisement.]

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, MAY 22, 1863.

PORTABLE ENGINE PISTONS.

The number of pistons under 2 ft. in diameter daily at work in Great Britain alone must be something enormous. Small stationary engines and locomotives can be counted by thousands; portable engines must be equally numerous; and leaving locomotives to take care of themselves, or rather, to be taken care of by the trustworthy hands in which they are placed, we may well devote a column or two to the consideration of the best piston for our greviously-wronged agricultural engines, which are generally placed under the charge of the most incompetent persons, and not unfrequently overworked to the last degree of endurance.

It is, perhaps, fortunate that the small diameter of the cylinders of these engines prevents the adoption of a very complex description of piston. Thirty or forty inches of area afford little space for any of that complicated paraphernalia which elevates a large piston to the dignity of an expensive machine. For the most part, makers have been contented with very simple forms of piston, which give more or less satisfaction, according to to the design and workmanship. The wisdom of this course is sufficiently evident. Were it otherwise—were complicated forms introduced—they would give rise to nothing but vexation and disappointment, as bad water and constant priming would destroy them in a few months. Agricultural engines are worked on a system peculiarly trying to both piston and cylinder; worked, perhaps, pretty constantly for eight or nine months during the threshing season, most usually with water so foul that priming is unavoidable, the piston becomes filled with dirt and grit, forced under the pressure of the steam into the minutest cranks and crannies, where it remains to rust and corrode every particle of metal with which it remains in contact during the three or four summer months that the engine stands, as completely neglected as though it were a useless piece of lumber which would never be needed again. As no attempt is made to cleanse or dry the cylinder at the termination of the threshing season, irreparable mischief too often ensues. We frequently find the piston rusted fast in the cylinder when the engine is again wanted, rendering a new piston and the reboring of the cylinder matters of absolute necessity; even at the best of times, a complex description of piston would be utterly unsuited to the working conditions of such engines. It may well be imagined, then, that the construction of pistons which will last and give perfect satisfaction is a question of very great importance to portable engine builders.

An attempt to describe, in even general terms, all the varieties of piston, simple and complicated, which have been introduced from time to time, would vastly exceed the limits at our command; we must, therefore, confine ourselves to a few of the most simple, suitable, and generally used.

We need hardly say that the old-fashioned hemp-packed piston has become one of things "that were," although the durability of hemp under very trying circumstances is sufficiently remarkable. We recently saw an old 12-horse power condensing engine taken down; seventeen years had elapsed since it had made its last revolution, yet on an attempt being made to remove the piston of the air pump, it was found quite air tight with the aid of a little water which lay on it; the packing was found on its ultimate removal to consist of a common hemp gasket, nearly sound, although the rod was almost eaten away by rust. The metallic packing of the steam piston, we may remark, was totally worthless from corrosion. We merely give this as an instance of the durability of hemp, without for a moment advocating a return to its use as a piston packing.

A form of piston early adopted in portable engines, consisted of a simple ring of brass, cast-iron, or steel, cut through at one place, in such a manner that no direct joint existed parallel with the piston-rod. This ring was forced against the cylinder by its own elasticity, aided by that of a circular steel spring, coiled up within it. The body of the piston was made in two parts, which, when put together and made fast on the rod by a nut, left a suitable groove between them for the packing ring. This piston was moderately simple, and has done good service; its great defect being wear at the edges of the ring, owing to which in a year or so it becomes too narrow for the groove, and permits the body of the piston to slip within it at each stroke, leading not only to its gradual destruction, but early permitting an excessive leakage between the ring and the body of the piston; two rings of the same kind have been employed in the length of the pistons with no better results. This piston may be daily met with still and, being very cheap, seems likely to hold its place.

The "Swedish" piston has given much satisfaction when employed in locomotives, and would be well worth a trial in portables. It consists of a solid body, in which two grooves, about half-an-inch square in section, are turned; into each groove is sprung a plain cast-iron ring cut straight across at one place, the elasticity of the rings giving all the spring necessary to make the piston tight. It is said to wear very well, but seems to us to be open in some degree to the same objection that applies to the last.

Ramsbottom's piston has lately met with much favour for locomotives. It consists of a solid cast-iron body, into which three square grooves are turned, varying in depth and width with the size of the piston. In ordinary portables these grooves measure about one-fourth of an inch each way; into these are sprung square wire rings, made of mild steel, of such a size that they fit the groove loosely, making a tight piston by their own elasticity. However well these pistons answer in locomotives, where the rings are much stronger, and are frequently examined and replaced by skilled hands, they are quite unsuitable for agricultural engines, being subject to rapid wear from the very small rubbing surface they offer to the cylinder. We have seen a set worn out in less than a month; they seldom last two; and in addition, are very liable to turn round on the piston, so that one end sometimes springs into the port, invariably breaking the piston as a result. It has been urged that the nominal cost of these rings, and the ease with which they can be replaced, constitute important advantages. All this we admit, when the engine is placed in skilful hands; but we have never met with an agricultural labourer who was competent to the task; the agricultural labourer and the agricultural engine invariably go together, and as these engines frequently find their way into remote districts, the inconvenience and expense of sending for a properly qualified person is sufficiently obvious to prevent their general adoption. Besides, these rings are very apt to set fast in the piston if bad oil is admitted to the cylinder; in which case, of course, the piston becomes a mere solid block; *apropos* of which we may mention that a solid piston was introduced a few years ago, constructed on the following principles:—The inside of the cylinder is very accurately bored, and the piston turned so as to be a very accurate fit; a few shallow grooves are then turned in it, in which a little water lodges, and is said to make the piston perfectly tight.

A very excellent piston is made thus:—A body is cast in two parts, turned, and fitted on the rod, so that when secured with a nut and lock-nut, they leave a groove between them; for a 10-inch piston, three-fourths of an inch deep, and two inches wide. A short cylinder of hard, tough, cast iron, of suitable size, is then chucked in a lathe, and has three rings successively cut from it. The external diameter of these rings is about half an inch greater than the bore of the cylinder. Two of them are turned with one straight and one sloping side, so that the cross section resembles a right-angled triangle with part of the apex cut off, the rings being about ⅝ of an inch thick, ¾ of an inch wide, on the outside, and ½ inch wide on the inside. Our readers will understand that these rings are placed in the groove of the piston in such a way that the straight side of each comes against the top and bottom plates respectively of the piston, leaving a space between them ½ an inch wide next the cylinder, and 1 inch wide next the body of the piston. The third packing ring is turned so as exactly to fill this space when put in position between the other two; its cross section being that of an isoceles triangle with the apex cut off, 1 inch wide next the body of the piston, ½ inch wide next the cylinder, and ⅝ of an inch thick; various other relative dimensions may be employed, but these will answer the purpose of illustration. The effect of the arrangement is, that the middle ring presenting but ½ an inch of surface to the cylinder, wears away much faster than the other rings which present ¾ of an inch each, and consequently pressing outwards, forces the other two rings laterally, owing to its wedge shape, against the top and bottom plates of the piston, so as to effectually provide for end, as well as surface wear. We have said that the rings are made larger than the cylinder, and when finished they have just so much cut out of their circumference as will permit the ends just to meet when placed in the cylinder. Their own elasticity is found amply sufficient to press them against the cylinder, so as to be perfectly steam-tight. The middle ring is sometimes made of brass, an unnecessary refinement.

All things considered, we do not believe a better packing for pistons up to 30 in. diameter can be adopted. From the strength of the rings, it is almost impossible to set them fast; indeed, it is difficult to see how any foreign substance can force its way between them. Once ground slightly together, they always remain in steam-tight contact until completely worn out. The piston is cheap, strong, durable, and unpatented. Indeed we believe it to be a very old invention. It deserves far more general adoption than it has hitherto met with.

Proprietors of portable engines would do well to remove the back lid, and thoroughly coat the inside of the cylinder with good tallow while it is yet warm, if there is any chance of the engine standing idle for a few months. The increased durability of the piston will well repay the extra trouble. Where the engine-driver is intelligent, he might soon learn to remove the piston and clean and oil it from time to time, thus preventing much of the mischief and expense too often incurred by want of care and attention on his part.

INDICATOR CONSTRUCTION.

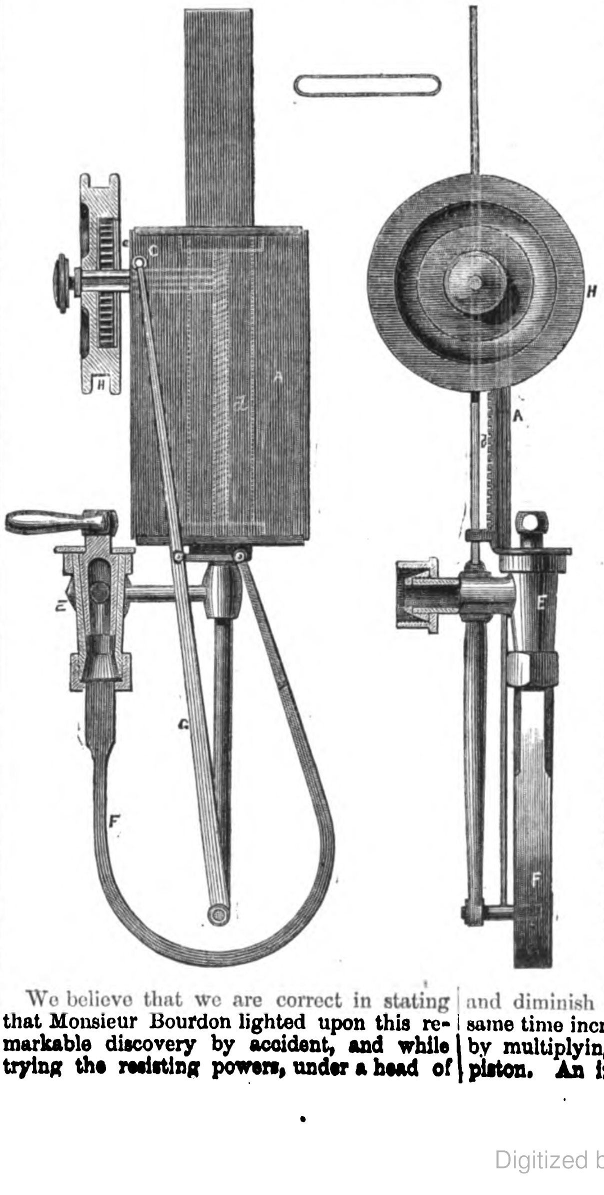
The indicator is an instrument of such importance to the steam-engine, that an improvement on it is almost equal in importance to an improvement on the steam-engine itself. At the death of Watt the use of the indicator declined for some years in England; this instrument was not generally known of, or if known, not appreciated by the other makers, and, as a natural result, the engines from the Soho Foundry still kept up their relative superiority. Indeed, it may be stated that the use of the indicator seems to have progressed in a parallel line with the improvement in the economy of the steam-engine itself. We look forward to great economical improvements in engines working at high pressures and speeds, coincident with the general adoption of an indicator that will register, with complete truth and accuracy, the action of the steam in the cylinders of this class of steam-engines.

At page 481 of Mr. Farey's old but still valuable book on the Steam-engine, will be found a short account of the progressive development of the indicator. The first indicators made by Watt could not take regular diagrams, being made without a pencil and paper to register the action of the steam at different parts of the stroke. This instrument was then merely a kind of combined steam and vacuum gauge; and the performance of the engine had to be roughly ascertained by a practised eye following the up-and-down motion of the pointer along the index. Mr. Farey states that he was unable to learn who first traced a *card* by means of the indicator, and in Watt's short description of the indicator in his Appendix to Dr. Robison's article "Steam-Engine," Watt makes no mention of the diagram. The first application of the pencil to trace a curve was, however, made at Soho; and it is conjectured by either Mr. Southern or Mr. Creighton, the well-known assistants of Watt. At first, the card was fixed flat against a small moveable tablet, placed vertically in a grooved frame. The tablet was moved to and fro at right angles to the motion of the piston rod of the indicator, by means of a string connected to the engine. Mr. Farey's work on the Steam-engine was first published in 1827; and he makes no mention therein of the revolving drum as at present used for the indicator, and so we may conclude that this improvement has an ulterior date to 1827. Mr. Farey advises a size of indicator with a piston 1.95 diameter, thus giving 3 square inches area. He regrets that, at the time he wrote, the indicator was neglected by the engine-makers of the day. Even up to 1838, the steam-engine indicator was but comparatively little known. In the Mechanics' Magazine, Vol. 28, for 1838, will be found an abstract of a paper by Mr. Henwood, giving an account, as a novelty, of an indicator used in Cornwall to get at the duty of the pumping engines in that county.

The two forms of the indicator most generally used in England, are those known under the respective names of M'Naught and Hopkinson. In the M'Naught indicator the barrel for the paper revolves on a bracket fixed to one side of the instrument. This indicator is thus more convenient to handle; but it is alleged that "it is not sensitive enough to show the true action of the steam upon the piston of the engine, because the pencil-holder, with the pencil in the position described, acts as a lever with a motion opposed to the motion of the piston, and adds additional friction." On the other hand, the moving parts of Mr. M'Naught's indicators are made as light as possible, in order to diminish any injurious action on the diagram of quickly reciprocating parts. The revolving barrel for the paper is placed outside the cylinder of the Hopkinson indicator. It will thus be seen that there is little difference in general construction between the M'Naught and Hopkinson indicators. The only differences that really give the relative value of the two instruments as compared with each other, would be the quality of the workmanship and materials, the greater or less weight of the working parts, and the more or less accurate way in which the degrees of the scale are obtained, &c.

Mons. Bourdon, of Paris, whose steam-gauge is so extensively introduced, and whose stand in the Western Annexe of the International Exhibition, offered quite "a carnival" of ingenuity, manufactures a peculiar kind of indicator, the motive principle of which is the the same as that in his steam-gauges. As is well known, he uses a tube, the transverse section of which is of an elliptical shape, or, in fact, of any other form but that of a circle, and the tube is itself bent, generally into the shape of a horse-shoe. The effect of the internal pressure causes the elastic tube to approach to the circular form of section, and this action has a tendency to straighten a bent tube; or, *vice versa*, to bend an irregularly shaped but straight tube.

BOURDON'S INDICATOR.



We believe that we are correct in stating that Monsieur Bourdon lighted upon this remarkable discovery by accident, and while trying the resisting powers, under a head of water, of some leaden pipes. Monsieur Bourdon has even used one of these flattened tubes to drive a small crank and fly-wheel, the return stroke being effected by the bending back of the elastic flattened tube on the steam being withdrawn. The accompanying cut shows his peculiar indicator, in front and side elevation. The stopcock E is in communication with the cylinder of the engine being indicated, and the steam thus enters into the bent flattened tube F; the other end of which is connected to the long arm G, turning on a pin below, and carrying the pencil *c* at the top. The pencil thus moves in an arc, and it leaves its mark on the paper fixed on the flat plate A. Behind this plate a rack *d* is worked by a small pinion. A wheel *e* and a pulley H are fixed on the axis of the latter, and a string is wound on the pulley H to get the progressive motion from the engine by moving the plate A up and down. The section of the pipe is shown on an enlarged scale, at the top of the engraving. This indicator, however, is accused of a want of sensitiveness; the spring is said to require time to follow up the action of the steam; some appearances thus pass unregistered, and these difficulties, of course, increase in proportion to the speed of the steam-engine piston. It is just possible, however, that the difficulty might be got over by increasing the size of the tube. We have not seen any indicator of this description at work in England.

It is evident by the engraving that the scheme is in several respects very incompletely carried out. Thus, it will be seen that the pointer moves in the arc of a circle; which could be avoided by means of a parallel motion. A revolving drum could then be used. All this is said upon the assumption that the sensitiveness required in an indicator could be obtained from this kind of tubular spring; a fact, however, that could easily be ascertained by examining the behaviour of the ordinary Bourdon steam-gauge under sudden alterations of steam pressure.

Mr. A. M. Perkins used, for very high pressures, an indicator constructed somewhat like the common instrument as regards its cylinder and piston, but in which the pressures were denoted by means of an index moving round a divided dial plate, like a spring balance.

Ever since the more general introduction of engines at high speeds, the want has been felt for an efficient indicator for this class of engine. Especially in engines with a rapid stroke, the oscillations of the spring caused by the sudden influx of the steam have proved a serious obstacle to the attainment of exact experimental data. This has been more particularly the case with locomotive engines, working at, say 220 revolutions per minute, with, perhaps, 100 lb. or 150 lb. pressure of steam on the pistons. The obvious remedy would be to increase the stiffness of the spring and diminish the range of the piston, at the same time increasing the scale of the diagram, by multiplying the stroke of the indicator piston. An instrument on this principle was designed some years ago by Mr. Gooch, and was employed by him in conducting the experiments in train resistances upon the Bristol and Exeter Railway. A fully illustrated account of this indicator will be found in Mr. D. K. Clarke's work on Railway Machinery. It may be briefly described as consisting of a small cylinder pressed down by a double elliptic spring; the short stroke of the piston being magnified by a lever. The pencil thus moves in the arc of a circle, which is an objection, as these arcs have afterwards to be reduced to straight lines. A continuous web is driven by clockwork, in order to take the pencil lines. There thus exists the danger of irregularity, incidental to all such contrivances; while there is no absolute certainty that the paper always coincides with the motion of the engine. A continuous web of diagrams is obtained; but the complication of the contrivance itself, and the trouble and loss of time incidental to reducing the diagrams, would always preclude a general introduction of this instrument.

An indicator that has lately been attracting great attention is one known under the name of the Richards' Indicator. It will be found fully described and illustrated in our Number for January 2nd, page 10. It is an American invention, and has been patented in this country by Mr. C. T. Porter.

It may be stated that the Richards' indicator is a much-improved and much-simplified form of Gooch's indicator; it is constructed upon the same leading principle—viz., that of obtaining a diagram on a large scale with a small stroke of piston, that the momentum of the spring and the moving parts may not exercise its necessarily injurious influence on diagrams that have to be taken at high speeds. It will be seen that the pencil is made to move in a straight line by means of a simple parallel motion; there is thus very little additional complication added to the common indicator, as the ordinary revolving drum is used. By the diminished throw of the piston (one-fourth that of the pencil), the friction is much lessened; while the short, stiff spring is not liable to rub against the sides of the cylinder. The piston of the Richards' indicator has an area equal to one half of a square inch. The different springs for the different pressures are easily taken in and out of the instrument, and the diagrams are 3½ in. by 5 in., and they are drawn on metallic paper by a metallic pencil. It appears to us that this indicator is not merely the only practical instrument for high speeds, but is also better than the ordinary indicator for slow-speed engines; though, of course, in this latter case, its advantages may not be so peculiarly felt. We understand that the Messrs. Elliot, the well-known instrument makers, are manufacturing these indicators on an extensive scale. We have previously alluded to the necessity of testing indicator springs while under the influence of heat. The Messrs. Elliot have, for instance, lately found that steam at 86 lb. pressure lessens the stiffness of Richards' indicator spring to the amount of no less than 2½ lb. The annexed diagrams will speak for themselves. They were taken by the Richards' indicator on the 22nd of last April, from the locomotive "Eagle," on the London and South-Western Railway, and we are permitted to engrave them by the courtesy of Mr. Beattie. The diagram shown by fig. 1 was taken with the reversing handle on the first notch, the steam being at 114 lb. pressure, and the locomotive working slowly ahead. Diagram, fig. 2, was taken also on the first notch, but the engines were working at the rate of 260 evolutions, while the steam pressure was equal to 105 lb. on the square inch.

Continuous indicators, or instruments that not merely ascertain but also register the work done by an engine, have at various times been introduced to the engineering public. An efficient and simple instrument of this kind would be of the utmost value, but we do not know of any one that has achieved more than a temporary success. The complication of these instruments, and the resulting trouble in their use, have prevented a general adoption of this description of registering apparatus.

Half size, twice over.

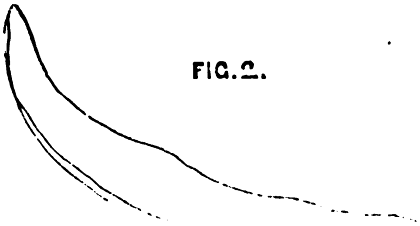

FIG. 2.

Half size, twice over.

A report of a Paper read by Professor Moseley, March 22, 1842, before the Institution of Civil Engineers, on the results of a trial of his Constant Indicator, is given in the MECHANICS' MAGAZINE of 1842, Vol. 37, page 35. This instrument, though highly ingenious, was a failure through its complicated arrangement. We will transcribe the following interesting remarks on indicators generally, made by Professor Moseley in the course of his lecture:—"The indicators originally used by Boulton and Watt were of a large size, with a long and powerful spring curled into a cylindric form, as large in diameter as could be included in the cylinder of the indicator, and the motion allowed to the piston by the spring was very short; such indicators were judiciously proportioned, and they do not show any sensible inequality of division in their scales. But, recently, indicators have been frequently made without the knowledge of their true principle, and the rules of proportion are not observed; so that it will sometimes be found, on actual trial of such instruments with weights, that their scale of pounds per square inch is not in equal divisions, although it is usual to employ a scale of equal divisions for running up the curves traced by them. In Boulton and Watt's indicators the scale of pounds per square inch was formed from actual trial with weights; but such trials were made when the indicator was cold, and dismounted from its place upon the steam-engine. A much better mode is to apply the weights in the upper end of the piston rod when the indicator is placed on the cylinder of the engine, while it is hot, its piston being supplied with the same quantity of oil, and the spring being in the same state as when it is in use. The depression of the piston by the weights is marked by drawing a line with the pencil of the instrument on the card itself, in the same manner as the usual atmospheric line is drawn thereon. A series of lines thus drawn with given weights, become so many original stages for subdividing between them, to form a true scale for running up the curve described under the same circumstances, and nearly at the same time."

About twenty years ago a grant of £100 was made by the British Association for the construction of a locomotive indicator, upon the principle of Professor Moseley's constant indicators, but we do not know with what result. Dr. Lardner once brought a peculiar continuous indicator under the notice of the British Association. Pencils of different colours were acted upon by floats placed in syphon tubes of mercury connected to the steam pipes, condenser, &c., and an endless web of paper took off the impressions of the different pencils. This instrument has also been abandoned.

While upon the subject of indicators, we may allude to a small instrument, which, we think, might be very useful to those having ofteh to calculate from indicator diagrams. After one of the meetings of the Institution of Civil Engineers, in March, 1853, Mr. Hulford, of H.M.'s Dockyard, Woolwich, exhibited a simple instrument of his invention, for ascertaining from an indicator card, the gross steam pressure on the piston. We are surprised that this simple contrivance is not more generally adopted. The following is its description as given in the Transactions of the Institution:—"The indicator card being placed on the board, so that the atmospheric line coincided with the marks on the returning figure, and the side roller made to revolve, until the spiral line on it intersected the edge of the scale, in which position the roller was fixed. The distances between the steam and vacuum lines were taken, by sliding the scale along the figure, and ten or twenty divisions might be taken, according to the degree of accuracy required; the sum of the distances, divided by their number, gave the mean pressure on the piston.

H.

THE QUALITATIVE RETROGRESSION OF THE IRON MANUFACTURE.

THE general depreciation in the quality of iron is getting a serious question. Numerous accidents by sea and land are ascribed by the papers to bad and untrustworthy iron. The nearest ironmonger's shop will tell a similar tale. The African explorers, Dr. Livingstone and Mr. Du Chaillu, tell us that the negroes of the interior of Africa reject, with a grin of contempt, any European iron that is offered to them, preferring their own excellent material, produced direct from the ore, and without any flux, by means of a rough apology for bellows, and worked out by a rude hammer of stone. The fuel used by the negroes is charcoal, and the iron thus smelted is preferred by them to the iron produced by all the appliances of civilization. In the pride of our superior knowledge and power, we often contrast the present state of the arts with that existing in the times of our remote ancestors. As regards quantity of production, we are immeasurably ahead; not so much, however, when quality of produce is taken into account. An excellent figurative contrast between the iron making of the middle ages and of modern times is afforded by a comparison of the "armour platings" of the two periods. It will be an amplification of a sentence in the Inaugural Address to the Institution of Civil Engineers, delivered by Mr. Hawkshaw, January, 1862, in which he says, in reference to our own times, that they form "a new era and another age, when ships, like knights of old, are to go forth to battle in complete armour, and when the civil engineer has assumed the duties which devolved on the smith and armourer of former times." The antique armour, still extant in our museums, shows a skill in the working of iron and steel that has been unsurpassed, even in these latter times of the division of labour principle. The quality of the metal employed is very fine, and shows great toughness and malleability. These armour plates are also often inlayed with gold or silver, in exquisitely designed patterns, and the lines in these patterns were sometimes fitted up in a peculiar way, with a dark composition. *Our* armour plates are on a greater scale; enormous slabs, like the one lately rolled out at Sheffield in presence of the Lords of the Admiralty; but the structure is scarcely homogeneous, and the quality lags far behind the exquisitely tough charcoal iron of the Middle Ages.

In attempting an investigation into the *ultimate* causes that affect the quality of iron, and confining ourselves to cast iron more especially, we are struck by the want of definite knowledge of experienced practitioners and writers on the subject. We mean by *ultimate* causes the influences that are strictly independent of profit and loss in the manufacture, such as the chemical constitution of the iron and the molecular structure involved therein.

The low quality of iron is ascribed by many to the use of mineral fuel in its production; this is, in fact, the most popular and generally received opinion. Undoubtedly the Swedish iron, produced from a very pure ore (the magnetic oxide of iron), and smelted with charcoal only, is the purest iron in the world. Like the charcoal iron of Styria, its production is limited, as the ironmasters are only allowed to burn a certain quantity of trees per annum. The charcoal iron of Nova Scotia does not lie under such restrictions, but in course of time the destruction of the wood forests will sooner or later set very limited bounds to its production. The results of the smelting and puddling operations, and the consequent purity of the iron, of course intimately depend upon the fuel employed, both as regards its chemical constituents and its powers as a combustible. What may be termed the vegetable fuels, charcoal and peat, are the freest from the mineral substances, such as sulphur, phosphorus, silica, &c., the union of which with iron is thought to exercise a more or less deleterious influence on its strength. The heating powers of charcoal and peat are only slightly inferior to the best kinds of mineral fuel, such as the Durham and anthracite coals. Attempts have been made by ourselves, while on the Continent some years ago, to utilize the lignite coal (called Braunkohle by the Germans) for working iron. This coal can be converted into a kind of charcoal in the same way as wood; unfortunately, the blocks of coal crumble to pieces under the process; and although such small pieces may be used for forging iron, it would be impossible to use fuel in a minute state of subdivision for the blast furnace. We have heard that similar attempts have been lately made with the lignite that is found at Bovey Hatfield, near Exeter. We consider that certain means might be easily adopted to overcome the difficulty of the coal crumbling to pieces while being coked. A successful solution of this problem would be of immense value in such countries as Austria and Prussia, where lignite coal is the principal fuel, and the only one in sufficient quantity to utilize the large deposits of iron ore to be found in those districts.

As we stated above, the great value of vegetable fuels in smelting iron, has been ascribed to their comparative freedom from mineral substances. Sulphur is, however, often present in the ashes of wood, as well as in many of the limestones used as flux. Besides, the well-known chemists Berthier, Janoyer, and others have shown that the quantity of sulphur in finished iron is not always in proportion to the sulphur combined with fuel and flux, but rather depends upon the mode of manufacture; such as the proportion of lime in the flux, the temperature of the furnace, the relative proportions of the charge, and other conditions. The precise deterioration caused by the presence of foreign mineral substances in iron, is still a matter of uncertainty, and it has even been stated that the Swedes throw pyrites (sulphuret of iron) into the furnace in order to produce a fine, gray, mottled iron for gun-founding. M. Janoyer's "Annales des Mines," 4 ser., t. xx., p. 359, has shown that sulphur and carbon combine in the blast-furnace, forming sulphuret of carbon, which becomes volatilized. This is the explanation that many of our English "makes" of iron are freed from any sensible traces of sulphur by means of properly working the furnace; although, as it is well known, most British coals contain sulphur. There is little doubt that the presence of sulphur has a deteriorating influence on iron. British coals appear to contain from 0·2 per cent to 2 per cent. of sulphur. As the result of a lengthened experience, Mr. Truran considered that iron was always more or less injured by the presence of any foreign substance. "The presence of carbon, by lowering the temperature of fusion, increases the fluidity of cast metal; but the qualities of hardness and tenacity are reduced in nearly the same ratio. Silver, in quantity, seems to impart additional hardness, but is attended with an equally great deficiency of tenacity, and materially impairs the ability of the metal to withstand crushing and abrading forces." The efficacy of improving iron by the addition of wrought-iron scraps to cast-iron in the cupolas is not denied by Mr. Truran; but he limits its employment to cast-iron of a low specific gravity. He states, "Iron possesses the greatest density and tenacity when pure; the presence of any other metal or matter, or mixture or alloy, reduces its density and diminishes in a more rapid ratio its tensile strength. The crude iron of commerce ordinarily contains about 80 per cent. by volume of metallic iron and 20 per cent. of impurity, is uniformly specifically lighter than pure iron, and possesses a very low degree of tensile strength. "The extent to which this property is deteriorated by the quality and volume of the alloy is a subject of paramount importance to the manufacturer and consumer of iron, but one in which, hitherto, owing to its costliness and extreme delicacy of manipulation demanded in the inquiry, no adequate experiments have been made. By a limited series, we ascertained that the tenacity in the various stages of manufacture was nearly in the ratio of the tenth power of its specific gravity." The superior tenacity of some of the foreign irons has been ascribed to charcoal, their purity, and freedom from admixture with foreign matters. Nevertheless, that the use of charcoal does not always denote great strength may be evidenced by some experiments conducted by the late Mr. Tierney Clarke, C.E., on the strength of Hungarian and Austrian charcoal cast irons. Mr. Clarke proposed to subject these irons to a transverse strain, in the construction of his beautiful bridge over the Danube at Pesth, the Hungarian capital. A general average of five different Hungarian and Austrian charcoal irons gave only 785·253 lb. to bars 1 in. square, subjected to a transverse strain, reduced to bars of 3 ft. bearing. The load was in the middle. All the irons were cold blast. Some experiments on English cold blast iron, quoted by Barlow, gave a mean of 844 lb.

There is little doubt that, by the exercise of a proper amount of skill, the degree of quality of our British iron would not lag so much behind the quantity produced. It is stated that the Belgian pig-iron has been greatly improved by washing the coal, so as to oxidize the pyrites, and convert it into copperas, which runs off in solution. This process would probably injure our coal, unless previously coked. At the same time, it appears to us that if the coal were charged into the furnace but a short time after being washed, very little injury would result. Most British coals deteriorate in quality when lying exposed to the air. They lose a considerable amount of their heating power; they disintegrate and crumble to pieces. Within six months' exposure they lose more than one-half of their iron-melting powers. At the same time, the presence of water in the blast furnace has undoubtedly a prejudicial influence on the "make" of iron. It has been calculated that, in ordinary seasons in England, 100 tons of water are discharged per week into the blast furnace through the tuyeres. This amount would considerably exceed the moisture that might remain on the surface of coal after the process of washing.

The most experienced ironmasters believe that the quality of iron is principally dependent on the fuel employed in its reduction. If the coal contains an insufficient quantity of carbon, or a large percentage of sulphur, it is unfit for smelting the superior "makes" of iron. Coking coal necessarily more or less drives off the sulphur; but for the latter to be completely volatilized the temperature of combustion is required, which is only undergone by the coal during its sojourn in the blast furnace. A portion of the carbon of the coke is consumed if the coking process be carried too far, and the result is a coke containing an undue proportion of ash and a diminished quantity of carbon.

The chemical composition, and the preparation of the limestone flux, also exercise considerable influence on the quality of the iron. It often contains sulphur, and always clay, silica, and other earths. It ought always to be broken into small pieces before being filled into the furnace. The best way of treating the limestone is to subject it to calcination, and then to at once convey it from the kiln to the furnace before its strong hygroscopic properties can absorb the moisture from the atmosphere.

We hope to return to this subject; but, in the meantime, we may state our firm conviction, as a result of a careful consideration of the conditions affecting the iron manufacture of Great Britain, that there is no physical reason why the general quality of British iron should be so inferior as it undoubtedly is at present. The use of a pure fuel like charcoal, and of pure ores like those of Sweden and Acadia, undoubtedly facilitate the production of good iron, merely because there is less chance of any want of skill influencing the result. The production of equally good iron by means of our English ores and coal, is simply a question of greater skill. No physical impossibilities intervene in the way of our ironmasters; let them but give as much attention to quality as to quantity, and the produce of our ironworks would be no longer as unsound in its nature as it is huge in its amount.

The quality of iron so intimately depends upon its chemical constituents, and upon its molecular structure, and both of these are themselves so much influenced by the mode of manufacture, that the exact relative bearings of all these influences will be difficult to ascertain. On examining a piece of iron which has given a certain definite result as to resistance, we ought to ask several questions—How has it been manufactured, and from what ores, flux, and fuel? What is its molecular structure? What are its chemical constituents? Only a practical iron-maker, and a thorough chemist, could answer such questions propounded by an engineer or user of the material. It appears to us that the important inquiries involved in the make and use of iron can only be solved by a scientific commission composed of engineers, chemists, and manufacturers; of those who most largely use and of those who manufacture iron. At present we have only the records of the disconnected experiments of a few individuals, often eminent men, it is true, but necessarily limited in their endeavours by the means and the science at the command of a single individual. "Non omnia possumus omnes."

INSTITUTION OF CIVIL ENGINEERS.

At the meeting of the Institution of Civil Engineers on May 12th, John Hawkshaw, Esq., president, in the chair, the Paper read was "On the Communication between London and Dublin," by Mr. W. Watson, M.A., Assoc. Inst. C.E.

Holyhead, the nearest point of land in Great Britain to the metropolis of Ireland, was naturally thought of at an early date as a convenient port of departure and arrival for the mails. This route had accordingly been used for a century and a half, and was recognized in an Act of Parliament passed in 1729; but the communication between London and Dublin was then irregular, and the time occupied on the journey protracted. Travelling through North Wales was attended with difficulty and fatigue, and the passage of the Channel was contingent on the state of the weather. Though measures of improvement were proposed before the close of the last century, no effectual steps were adopted, until after the legislative union had taken place between Great Britain and Ireland, in the year 1801. Then public commissioners were constantly engaged in inquiries, and committees of the House of Commons presented no less than twenty-five reports on the subject within ten years. These investigations had reference, principally, to the land part of the journey; and by means of large grants of public money, amounting, it was believed, to nearly one million sterling, in 1826 a continuous and easy road was completed between London and Holyhead, so that the entire distance of 267 miles could be performed, with regularity, safety, and comparative comfort, in 34 hours. Improvements for the sea-part of the journey also engaged some degree of attention; but while sailing vessels were in use, it was not thought that much could be gained in the passage of the Channel. In 1819, a steam vessel was placed on the Holyhead station for the summer and autumn, and soon afterwards the "Royal Sovereign" and the "Meteor" were especially built for the Post-office service, with engines by Messrs. Boulton and Watt, and then the sailing cutters disappeared. The average length of the passages of these two steam vessels, in the first year, between Holyhead and Howth, was 7 hours and 33 minutes; the shortest passage was made in 5 hours and 48 minutes, and the longest was stated to have occupied upwards of 23 hours.

The mail communication between London and Dublin had been thus long maintained exclusively by way of Holyhead; but the rapidly growing importance of Liverpool led to the establishment, in 1826, of a direct postal service between that port and Ireland. Steam vessels had been placed on that station, by private enterprise, as early as 1819, for the conveyance of passengers during the summer months; and in 1823, Mr. C. Wye Williams (Assoc. Inst. C.E.) originated a Company for the maintenance of a regular steam communication throughout the entire year, for the conveyance of passengers and of merchandise. As the railway from London to Liverpool was opened in 1838, that line became for some years the most expeditious route to Dublin, and the mails and passengers nearly deserted Holyhead. Liverpool did not long, however, retain this superiority; for, in 1849, a continuous line of railway was completed between London and Holyhead, by private capital, 23 years after the continuous line of road had been constructed, by direction of the State, and principally by grants of public money. The conveyance of the Irish mails was then transferred from Liverpool to Holyhead, and the large and powerful packets of the Government and of the Company, which had carried the night mail under contract for the previous ten years on the Liverpool line, were appropriated to other duties.

During the time these changes were in progress, the packet service was transferred from Howth to the Asylum Harbour, at Kingstown, which was ultimately connected with Dublin by a railway 6 miles in length. The only link then remaining to complete the communication with Ireland was a superior class of vessels. The Government having decided on building four vessels, each of 700 tons burthen, with engines of 350-horse power, the best result was admitted to have been attained; as the rate of speed of the "Banshee" at the measured mile, was upwards of 18 statute miles an hour, or nearly 4 miles in excess of any previously obtained. After a short trial of this service at heavy cost, the Lords of the Admiralty determined that it should be performed by contract, as had previously been the case on the Liverpool line, and that the average speed should be 12 knots, or nearly 14 statute miles per hour. This service lasted from May, 1850, until October, 1860, and was performed within the stipulated time.

Further improvements being still demanded, a plan was submitted to Government, and a new postal contract was entered into, the main provisions of which were, first, that the entire distance between London and Kingstown, instead of to Dublin, was to be performed in eleven hours, allowing four hours for the sea passage; secondly, that four steam packets should be specially built for the service; thirdly, that express trains should be appropriated exclusively to the Irish traffic; and fourthly, a morning and evening departure from each capital. The vessels referred to were each 2,000 tons burthen, and in their dimensions and general arrangements were nearly identical. Three, the "Connaught," the "Ulster," and the "Munster," were built by Messrs. Laird; and one, the "Leinster," by Mr. Samuda. The ships were of iron, timber having been used only for the decks and cabin fittings. The length of the "Connaught" between the perpendiculars was 334 ft., the beam was 35 ft., and the depth 21 ft. There were nine principal water-tight bulkheads, which not only provided for the safety of the ship in case of accident, but added greatly to the strength. The bulwarks were of iron plates, in continuation of the sides of the vessels, without any break for gangways. Between the paddle-boxes there was an upper deck, which further added to the strength amidships; and on this was placed the wheel and binnacle. The entire of the main deck, from the foremost funnel forward, was covered by a hurricane deck, which had been found of great advantage in throwing off seas in heavy weather. The engines in all the vessels were on the oscillating principle. Those for the "Connaught" and the "Leinster" were made by Messrs. Ravenhill, Salkeld, and Co. The cylinders were 98 in. diameter and 6 ft. 6in. stroke, the air-pumps being 54 in. diameter, with a length of stroke of 2 ft. 6 in. The boilers were multitubular, eight in number, four at each end of the engine-room space, arranged in pairs, with one funnel to each pair. There were five fire grates in each boiler, and the total grate surface was 677 square feet, the heating surface exceeding 19,000 ft. The wheels were 31 ft. in diameter to the outside of the floats, which were feathering, fourteen in number, and each was 12 ft. long by 4 ft. 4 in. broad. On the trial trips, the engines worked at the rate of 25½ revolutions per minute, with 25 lb. steam. The mean of the runs of the "Leinster," at the measured mile was 20½, and of the "Connaught" 20¾ statute miles per hour. The engines of the "Ulster" and the "Munster" were constructed by Messrs. James Watt and Co. The cylinders were 96 in. in diameter with a length of stroke of 7 ft. The wheels were 33 ft. in diameter. The boilers had each six fire-places, giving an equal extent of grate surface with the other. The heating surface measured 18,033 square feet. These engines were erected on board the vessels in the Liverpool Docks, and from a return of observations made on several trips, there being no measured mile at that port for testing speed, the rate attained appeared to have been 20½ statute miles per hour. One of the principal peculiarities which made these vessels of so unique a class, was the Post-office fitted for sorting letters on the passage, so that the letters were ready for delivery, or to be forwarded to their destination, on the arrival of the vessels, either at Kingstown or at Holyhead. About two hours were thus saved in the transmission of the mail.

The contract with the Postmaster-General had appointed January, 1861, for the commencement of the improved service. But as the vessels were in readiness some months sooner, it was commenced in October, 1860, and had since been continued without interruption. From what had been already stated, it would have been seen, that the difference of speed between the four vessels on the trial trips was inappreciable—a matter of paramount importance to a mail service. Thus, while the shortest passage of the "Connaught" across the Channel occupied 3 hours and 14 minutes, being at the rate of about 20 miles an hour, the shortest passages of the "Leinster," the "Ulster," and the "Munster," were 3 hours and 20 minutes, 3 hours and 18 minutes, and 3 hours and 22 minutes respectively. Their average performance for the two years and five months during which they had been on service, inclusive of the trips made in fogs, gales, &c., was still closer, as

The "Connaught" made 1,064 passages in 3h. 51½ m. on the average.
The "Leinster" made 919 passages in 3 h. 52¼ m. on the average.
The "Ulster" made 925 passages in 3 h. 55 m. on the average.
The "Munster" made 920 passages in 3 h. 58 1-10 m. on the average.

The consumption of coal in the first few months was considerably in excess of the quantity originally estimated. Steam of from 25 lb. to 28 lb. pressure was then used; but satisfactory arrangements had since been made to reduce the consumption, while the additional time occupied on the passage was but a few minutes, and was still within the time alloted to the sea service. The engines in the "Ulster" and the "Munster" had been provided with super-heaters, but experience had not shown any advantage, either as reducing the consumption of coal, or as tending to a superior performance. These vessels had made in the aggregate 1,845 passages, in the average time of 3 hours 56½ minutes, and had consumed 30 tons 7 cwt. of coal as the average of each inclusive of the quantity required for raising steam, which was considerable. The "Leinster" and the "Connaught," without super-heaters, had made 1,983 passages in the average time of 3 hours 52 minutes, and had consumed, inclusive of raising steam, on the average, 30 tons 1 cwt. of coal.

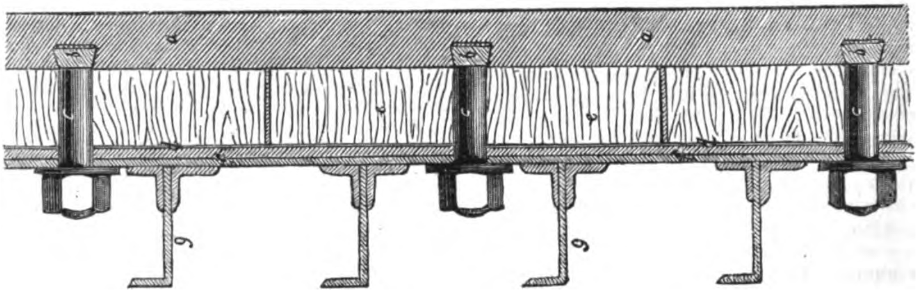
It was satisfactory to be able to state that the ships had, so far, needed no repairs, being now in as perfect a condition as when the service was commenced in 1860. The frequency of docking for the purpose of cleaning and coating, had afforded constant opportunities of examination, when painting only had been required.

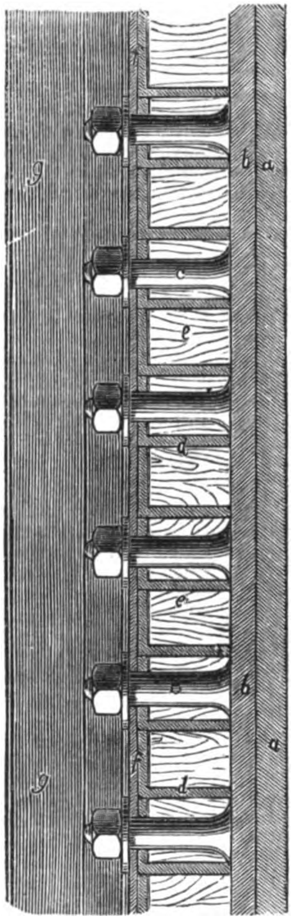
In conclusion, the Author referred to the admirable performance of the land portion of the journey, from London to Holyhead, by the London and North Western Railway Company; the punctuality in the arrival of the trains on the jetty at the latter place, the speed maintained, and the excellence of the carriages, were the subject of universal approval. Further improvements, at present not thought of, might yet be brought into operation; but there appeared to be no reason for apprehending, that the communication by way of Holyhead would ever cease to be the best for postal purposes, and to be preferred by the travelling public, so long as the entire distance between London and Dublin could be accomplished within eleven hours and a half.

IRON CELLULAR BACKING TO ARMOUR PLATES.

MR. GEORGE CLARK'S SYSTEM.

IRON CELLULAR BACKING TO ARMOUR PLATES.





THE trial at Shoeburyness of the experimental target, constructed by the Millwall Iron Works and Shipbuilding Company, on the system of Mr. James Chalmers, has created much interest in the departments which have to determine the best mode of armour-plating our sea and land defences.

Previous to this trial, in accordance with the reports of the special Committee on Iron, and the opinions of eminent scientific men consulted by the Government authorities, wood was considered to be the best material for backing to armour plates. All the iron-clad ships of the Royal Navy, built or under construction, have teak backing, varying in thickness from 18 in. for the "Warrior," to 9 in. for the "Minotaur" class. The principle relied upon was the absorption of the projectile force by elastic resistance spread over a large surface of solid timber. Experiments on targets constructed without wood backing, on plans proposed by the Iron Plate Committee, Mr. Samuda, Mr. Scott Russell, and Mr. Thorneycroft, gave results which were unfavourable to the rigid principle, but in all these cases there was no backing, properly speaking, to the armour plates.

For more than twelve months the defects of wood backing and the probable advantages of a rigid backing have been pointed out in the MECHANICS' MAGAZINE. Our last impression contained a description of Mr. George Clark's system in the form of a report of his observations at a meeting of the Institute of Civil Engineers so far back as February, 1862. Two years ago he submitted his ideas on the defects of elastic and the efficacy of rigid backing to the Admiralty, who, after considerable hesitation, eventually, at the reiterated recommendation of the Iron Plate Committee, on the 31st October last, authorized the construction of a target on Mr. Clark's plan at the public expense.

The Millwall Company, in the first week of November, contracted for the construction of his target. About two months afterwards, at the request of Sir Morton Peto, a partner in the Company, they undertook the construction of Mr. Chalmers' target, which, as our readers know, was completed and experimented upon three weeks ago. Some difference arose between Mr. Clark and the Millwall Company in consequence of the long delay in executing their contract with him; but the target, now nearly completed, is being fixed at Shoeburyness, and will in a few days be put to the usual test under the direction of the Iron Plate Committee.

The approaching experiments, of which the programme will, no doubt, be the same as that for the "Warrior" section, will probably determine the value of rigidity of construction for armour plating.

Mr. Clark is the uncompromising advocate for perfect rigidity. He has been consistently opposed to elasticity in any form, contending that in experimental trials the damage to armour plates and their fastenings was to be attributed chiefly to wood backing and elastic washers. Mr. Chalmers, to a certain extent, has applied Mr. Clark's idea of rigidity by the formation of iron cells at the back of the armour plates; but he, like nearly all the engineers, adheres to the principle of elasticity. To mitigate, or, in his own words, "to guard against the injurious effects of vibration, such as the fracturing of armour plates and the destruction of fastenings and frames of ships which are inseparably connected with very rigid structures," Mr. Chalmers introduces "*a cushion of timber planking*" between the rigid backing and the skin of the ship.

According to Mr. Clark's ideas, this "cushion" is a source of weakness. He contends that, as the wood must be crushed between the two iron surfaces, the cushion breaks the continuity of rigidity in the structure as a whole; and, therefore, the projectile force, meeting with no adequate resistance from the wood, is not "dispersed over an extended area," as it would be if complete rigidity were maintained all over and through the structure.

We give the arguments on both sides. They will soon be tested by the best of all arguments, actual experiment; and we think it creditable to the Government, even at this late hour, that they have determined to submit the rigid system, in opposition to a host of prejudices, to a fair trial. We learn with satisfaction that the Admiralty have agreed to pay the expense of Mr. Chalmers' target. It is, we understand, being dismantled at Shoeburyness, with a view of ascertaining, by an examination of the internal parts of the structure, the effects produced upon it by the severe pounding to which it was subjected.

The above engravings illustrate sections of Mr. Clark's target, showing his system of construction, which comprises not only his plan of rigid backing and back supports, but a mode of dovetailed fastening at the back of the armour plates, avoiding the use of through bolts and perforation of bolt holes in the plates. Serious doubts are entertained by engineers whether the dovetailed slots cut into the plates will not be a greater source of weakness than bolt holes. Mr. Clark's answer is:—1st. That, the heads of the bolts not being exposed to impact, the bolts themselves will not feel the force, and cannot act as wedges to split the plates. 2nd. That distortion causes the fracture of plates; and, as by his plan of complete rigidity and solidity of structure combined, distortion of the plates cannot take place, they will not be more liable to crack at the dovetailed slots than in any other part. Moreover, to obviate this objection, should it exist, some of the plates on his target are formed with ribs, into which the slots are cut, so that the body of these plates will not be diminished in thickness.

The following description of the drawings explains the details of construction:—*a*, *a*, The armour plates; *b*, *b*, dovetailed bars fitted into dovetailed slots cut into the plates; *c*, *c*, armour-plate bolts welded to the dovetailed bars; *d*, *d*, iron longitudinal cells, formed of angle bars, riveted to the skin and frames of the ship; *e*, *e*, filling to the cells, consisting of blocks of teak, with the grain end on, in some of the cells, and of millboard blocks in others, all tightly wedged in; *f*, *f*, skin plate of the ship; *g*, *g*, frames of angle iron, representing the ordinary ribs of an iron ship.

The weight, under the conditions prescribed by the Admiralty, is not to exceed the "Warrior" standard of 346·8 lb. per square foot of superficial area. Additional supports are allowed at the ends and the top and bottom to compensate the want of continuity, and maintain the rigid principle; but within those limits, the weight of every section of the target will be the same as that of the "Warrior."

It will be seen that the system is one of perfect rigidity and cohesion in every part of the structure. In this particular, it differs essentially from the Chalmers' plan, which, as we have shown, is a compromise between rigidity and elasticity. The mode of holding the plates, in the Clark plan, on parallel lines across their width, adds greatly to the adhesive area and screw power of the fastenings. The bolts are of 2½ in. and 3 in. diameter. Those of the "Warrior" are 1½ in. The feature of the plan chiefly relied upon, and of which Mr. Clark claims to be the inventor, is that the iron cells are less in width than the diameter of the projectiles. The area of the target is 13 ft. 6 in. long by 10 ft. in height without a port. The armour plates are seven in number, are of two lengths, 7ft. 6in. and 6 ft., and of three widths, 2 ft., 3 ft., and 4 ft., and they vary in thickness from 3 in. to 4 in., 4½ in., and 5 in., the breadth and depth of the cells increasing with the diminished thickness of the plates. According to Mr. Clark's theory, the real strength of the ship's armour is to be found in the strength and rigidity of the backing rather than in the thickness of the armour plates. He also holds, in opposition to the universal creed, that short plates are, with rigid backing, better calculated to resist projectiles than long ones, as the former admit of being more securely fastened and are less liable to buckle. The cells are 4½ in. and 5½ in. in width, the narrowest and deepest cells being at the back of the thinnest plates.

The experiments on this target, especially after the evidence of the efficacy of rigid backing furnished by Mr. Chalmers' partial mode of its application, will no doubt be regarded with interest.

GREEN AND COCKCROFTS MATERIAL TO BE USED IN LIEU OF PRINTERS' BLANKETS.

Messrs. Green and Cockcroft, of Accrington, propose to form an amalgamation of materials to be used as a substitute for printers' blankets. The material is formed by combining two or more lengths of paper together with a solution of india rubber or its substitutes by spreading it between them and pressing them together. Or a textile fabric may be placed between folds of paper, and treated with a solution as above.

In selecting the "surface" for the article to be used for printers' blankets it must be adapted to the peculiar colours used by the printer, as some colours are strongly acid, some alkaline, and others neutral.

The material is suitable for paper-makers if prepared with a textile fabric at the back; likewise for washers or packing for steam joints—when used for this purpose, any suitable number of any of the above materials are joined together and submitted to pressure and heat or other drying process.

GISBORNE'S ELECTRIC COMPASS.

Mr. Gisborne's electric compass, to which we have before called attention, is nothing more than the ordinary ship's compass, with a battery in the box, and two insulated wires maintaining the electric currents round the needle. This is the whole contrivance. This simple application of electricity supersedes the elaborate inquiries of the Astronomer Royal, the life-long mathematical labours of Mr. Smith, the philosophical observations of Mr. Evans, and the eminently practical experiments of the Liverpool Compass Committee. Hereafter compass variations need not appear in the loss of life and property, and the sailor may range the trackless ocean assured that he steers his course with safe precision. Captain Washington once made the remark that but for the labours of the Compass Committee, Mr. Evans, Mr. Smith, and the Astronomer Royal, it would have been impossible to send iron ships to sea. Mr. Scott Russell, at the same time, while reproaching himself and the shipbuilders of the country with the oversight of the compass, congratulated the officers and seamen of the fleet and the merchant service with the fact that, while he and the shipbuilders were doing their best to advance the science of ship construction to ideal forms, scholars, scientific and practical men, were constantly toiling to reduce the variations of the compass to intelligible and certain laws. At the next meeting of the Institution of Naval Architects, these gentlemen are likely to congratulate each other and the world, that further labour in that direction is superfluous, and that the application of electricity to the compass is, in one day, of as much importance in the safe navigation of iron and iron-built ships, as the invention of the compass was in early times. Iron ships and iron cargoes may be said to have deprived the sailor of the use of the compass; and the application of electricity to have restored it to him.

That the importance of Mr. Gisborne's simple application of electricity to the compass may be clearly understood, it may be well to state that the Liverpool Compass Committee, Mr. Evans, Mr. Smith, and the Astronomer Royal obtained from Mr. Fairbairn [illegible] plates, each [illegible] in. long, 4 in. broad, and ½ in. thick, to verify by experiment that the power of malleable iron for the reception and retention of subpermanent magnetism depends on the degree of heat at which the iron is passed through the rolls. "On collecting," he observes, "all the results (after repeated annihilations and revivals of magnetism) with the unlettered end downwards, the magnetism of the cold rolled longitudinal bars is greater than that of the other bars in the proportion of about 14 to 10; while those with the lettered end downwards are about 11 to 10." Here obviously we have a key to much that has been, and as to good and bad iron for the construction of ships the good iron being that which would lead to little compass variation, and the bad iron that which would lead to considerable or excessive compass variation. But the inquiries and deductions of the Astronomer Royal have been pushed much further. He goes so far as to recommend that iron ships should be built with the keel nearly north and south. The results of Mr. Smith's studies may be summed up in the one sentence that "the north end of the keel is attracted to that part of the iron hull which was furthest from the north in building." In other words, if the head of an iron ship is built towards the north, the needle will point towards the south; and if the head of an iron ship is built towards the south the needle will point towards the north; and so on—the general laws being disturbed and counteracted in endless ways. Mr. Evans again tells us that the "Warrior" was built head north 8 deg. east, and the armour put on head north-west; the "Black Prince" built head south, 20 deg. east, and the armour put on head south; and the "Defence" built head south, 47 deg. west., and the armour put on head south, 19 deg. east. He says, "The general law obtains in these ships that the point of the compass is drawn towards that part of the ship which was south in building." Mr. Evans has also told us the precise amount of compass variations: 1st, in sailing vessels, wood built; 2nd, in steam vessels, wood built; 3rd, in vessels built partly of wood and iron; 4th, in steam and sailing vessels, iron built; and 5th, in iron-plated ships. In a wooden sailing ship the north end of the needle is drawn to the ship's head, and the amount is small; engines and boilers increase the amount; and, as observed before, if an iron ship is built north, so great is the variation that the needle will point south. The ill-fated "Royal Charter" had a large amount of variation. Last of all, Mr. Rundell, on behalf of the Liverpool Compass Committee, tells us many things. He says "that many captains, finding the errors of their compasses constantly vary with change of latitude, dispense with compensation of any kind, and trust entirely to constant celestial observation for determining the amount and direction of these errors." But it is needless to enlarge. Up to the present time so much uncertainty has attached to the navigation of iron vessels from the variations of the compass, that it is a marvel so few iron vessels are lost annually, and so few of our brave seamen perish.

Mr. Gisborne's electric compass was tried recently for three days on board the iron steamer "Resolute" in the Mersey. It was uninfluenced by the iron of the vessel, and worked correctly when placed over the engines and between the chimneys. Not so the ordinary compass of the "Resolute" with the well-known magnetic adjustments; the variations being 1½ to 1¾ points. Piles of steel and iron shavings placed round the electric compass do not act upon the needle, and it is alike insensible to the presence of bars of iron on the top of the box. Tests such as these are demonstrations that currents of electricity restore the compass to the sailor as unvarying and trustworthy as when steam machinery, iron hulls, masts, and rigging were unknown. Mr. Gisborne is an eminent electrician, and having crossed the Atlantic frequently, it occurred to him to try electric currents as a means of checking compass variations. The thought was a happy one, and Mr. Gisborne is now to be regarded as one of the benefactors of mankind. The immediate and peremptory adoption of the electric compass would spare thousands of lives and value to the extent of millions every year.

LAUNCH OF A RUSSIAN IRON-CLAD.

On Monday afternoon the first iron-cased frigate for the Russian navy was launched from the yard of the Thames Ironworks, which has had the honour of building the first ships of this description for the English, Danish, and Russian navies, and which is now constructing the first frigates of the same kind for the navies of Spain and Turkey. The "Pervenitz," as the new Russian frigate was named, is probably one of the ugliest vessels that has ever floated from the yard of the Thames Works—not only uglier than the "Resistance" and the "Defence," but as ugly even as the much-vaunted American invention, the floating "Derrick," which has never had anything to do but float since the day she was launched. To see the "Pervenitz" as she was towed out of the creek, with her narrow receding sides and uncouth projecting snout, above which the red hawse-holes flamed like the eyes of a monster, she more resembled the quaint hideous forms of the Chinese junks than any European man-of-war we have yet seen in the Thames. This Russian frigate, which has been some time building, from designs furnished from Russia, represents with peculiar force the rapid strides with which the construction of iron frigates has advanced in this country within the last two or three years. At the time the "Pervenitz" was first thought of, all the world seemed in favour of using such armour-coated vessels mainly as steam rams, and, accordingly, the Russian frigate has been produced not only with a beak, but a monstrous projection under her bows and level with the water-line long enough and strong enough to transfix the stoutest three-decker that ever floated. In the same way a great angle of incline inwards for the sides was thought an absolute necessity for iron-clads to assist the shot in glancing, so the "Pervenitz" has her sides sloping in at an angle of no less than 27 deg.—an amount of incline which is an evil, in many ways, and which experience shows, even if it were increased to 45 deg., would have but little effect in diminishing the terrible powers of such ordnance as are daily tried at Shoeburyness. These drawbacks, the beak and the slope of sides, will prove serious obstacles when at sea; the former to her speed, and the latter to her steadiness in a seaway. Unlike the "Warrior," to imitate which she was ostensibly built by Russia, the thickness of the teak backing behind the armour plates is diminished from 18 in. to 9 in., though this disadvantage is, perhaps, on the whole, compensated by the reduction of weight, which enables her to carry her armour of 4½ in. plates from end to end and over her beaks (for she has two) at stem and stern. The total length of the vessel between perpendiculars, and exclusive of the beaks, is 200 ft.; her breadth, 53 ft.; depth, 26 ft. 6 in.; and the burden, according to the builder's measurement, is, in round numbers, 3,000 tons. When fully equipped for sea, her draught of water will be 14 ft., and the armament she is intended to carry is 28 68-pounders on her main deck, all protected by her armour plates, with two large pivot rifled 100-pounders on the upper deck. Thus armed and equipped, her portsills will be 6½ ft. above the water—nearly 3 ft. nearer the water than those of the "Warrior" class, and rather more than 1 ft. higher from it than the portsills of the once famous "La Gloire." With anything like tolerable speed, and fair weather to act in, the "Pervenitz" would be a formidable vessel. As it is, she will scarcely be formidable to sailing vessels, unless she catches them becalmed, for her horse-power, instead of being at least 600, is only 300, which, with the great displacement of her midship section, the bulk and weight of her huge beak under water forward, and the dead water she is sure to tow after her beak astern, all seem to show that even in her trial trip nine knots is likely to be her highest rate of speed. In a seaway we shall be much mistaken if she can command even this average momentum. The launch, as is usual with all the launches at the Thames Works, was managed to perfection. The Earl of Caithness, the Earl of Macclesfield, Lord Wenlock, Lord Richard Grosvenor, Mr. W. S. Lindsay, M.P., Mr. Ayrton, M.P., with a number of Russian officers, the directors of the Thames Company, and a large circle of invited guests, were present on the occasion. At 2 o'clock Miss Hume christened the vessel, and at once, without check or hindrance, she went down the slips into the water with perfect ease. On the water, as we have said, she looked intolerably ugly, and, what is more, seemed to show that she must prove a wet, heavy, and most uncomfortable boat in dirty weather. In a head sea her bows will always be awash, while the incline of her sides, or "tumble home," will facilitate to the very utmost her tumbling everywhere in a heavy swell. It was impossible to look at her whole form, at the designs for the construction of the Spanish and Turkish frigates, and then turn to the colossal shape, yet exquisitely fine lines, of the "Minotaur" building in the same yard for our navy, without feeling at once the almost immeasurable superiority in size, in strength, and in speed which the English ships of this class possess. Almost every iron-clad frigate or floating battery in the world, except the American failures and two frigates constructing in France for the Italian Government, is being built in England for foreign Governments. An impartial examination of all these varied plans and systems affords the most convincing proof that in size, speed, and strength our iron-clads are as much beyond those of foreign navies as our screw liners are beyond the old sailing 74's of 20 years ago. There is not a foreign iron-clad on which half as much money has been spent, ton for ton as with every economy we are obliged to spend on ours to make them perfect, and there is not as yet one foreign iron-clad which in real efficiency is worth a tenth of one of ours.—*Times*.

M'CARTHY'S AUTOMATIC SAFETY VALVE.

The accompanying engravings illustrate an invention recently patented by Mr. C. M'Carthy, of New York, for an automatic safety valve. The invention consists in so arranging the valve that on any excess of pressure in the boiler, steam and water may be blown into the fire-box by means of pipes, and thereby act as a damper. Below the valve seat a pipe C is connected, running downwards in the boiler to within a few inches of the bottom. When the boiler is in operation, the steam will force the water into the pipe C, and through the valve into the chamber B, and pass off by the pipe E into the fire-box. In the chamber B a spindle is arranged, passing through a stuffing-box through one side of the chamber. Upon this spindle is attached a lever, which acts upon the under side of the weight W, or upon a collar on the stem of the valve, so as to raise the valve when desired. Upon the end of this spindle, on the outside of the chamber B, a lever is fastened, through which the forked lever and valve may at any time be operated. The levers are so arranged that they will operate the valve only for the purpose of raising it, and without interfering with its free action. In the inside of the boiler a float L is arranged, floating upon the water, and provided with a rod passing through a stuffing-box in the top of the boiler. On the end of this rod a slot *m* is arranged, in which the pin on the end of the lever fits. This slot *m* is of such a length as to allow sufficient play without coming in contact with the pin, when the float L rises or falls according as the level of the water in the boiler rises or falls, until the float L falls to a certain point below the fixed water level, on account of the falling of the water to that point, when the top of the slot *m* comes in contact with the pin upon the lever, so as to operate the forked arm and raise the valve, when the water from the lower part of the boiler will be forced through the valve, escaping from the chamber through the pipes E, and be thrown upon the fire, thereby extinguishing the same.

By the above it will be perceived that by this arrangement the fire in the grate will be extinguished before the top flue plates will be exposed to any undue heat, consequently removing always all danger arising from a deficiency of water while the fire is in full operation.

From the above described arrangement it will be readily understood that this valve operates effectively in both cases, and from these most accidents in steam boilers result, namely, from an excess of pressure in the boiler, and secondly, from a deficiency of water in the boiler; and, at the same time, it acts in such a manner as to remove the primary cause of all accidents, namely, the fire, which, by the operation of this improved valve, is either deadened or quite extinguished.

As the float L works quite independently of the safely valve until the water falls below a certain point, it may be made to act as a water indicator, to show the level of the water in the boiler. A connection is in that case made between the float rod and a dial, or any other equivalent or similar mechanical contrivance.

M'CARTHY'S AUTOMATIC SAFETY VALVE.

FIG. 2.

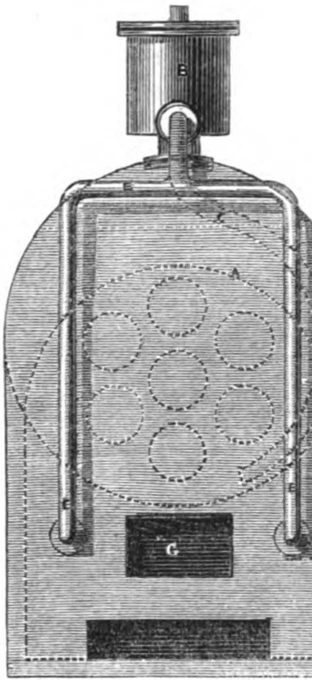


FIG. 1.

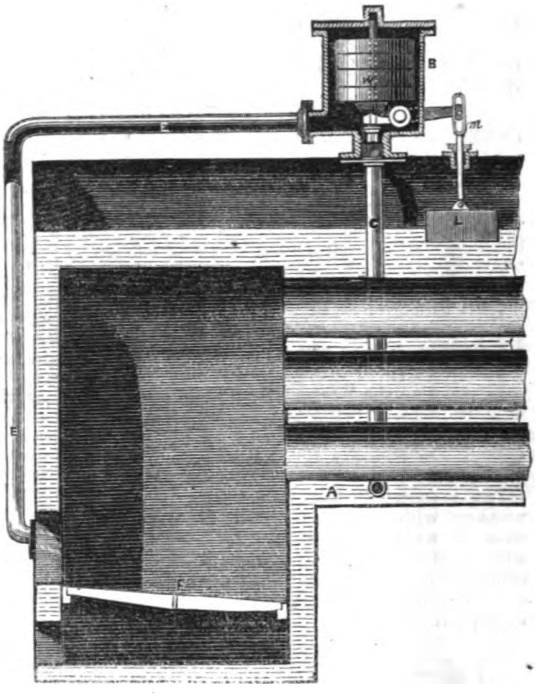

SHEDLOCK'S GAS-METERS.

This invention, just patented by Mr. J. J. Shedlock, of Cambridge-street, Pimlico, has for its object improvements in wet gas-meters. In order that a wet gas-meter may be rendered the more sure and perfect in its registration, the drum or measuring wheel is surrounded with an annular float or air-tight vessel of sufficient capacity to displace a volume of water equal in weight to the drum, so that by possessing a buoyancy it can rise as the water rises, or fall as the water decreases in the case, or, more properly speaking, that the water always mantains the same level in the drum or measuring wheel. The two ends of the shaft or axis of the drum pass through and are guided by a retangular frame or double lever, which is supported and carried by two fixed pivot or bearings forming the fulcrum. Upon one end of the lever or frame is secured a curved gas-holder, which is intended to neutralize the effect of the sudden entry of gas at a high pressure into the drum or measuring wheel. Upon the other end of the frame is attached a balance weight equal to the weight of the curved gas-holder. By the retangular frame or lever vibrating on the fixed points or pivots, the drum or measuring wheel is constrained to form an arc in following the variations of the water level. The frame is curved so as to allow the spout or the supply pipe to pass into the drum. The gas entering the meter passes through the inlet valve, which is attached to and acted upon by a small float resting upon and governed by the water in the case; the gas then passes through a second valve, which being suspended, is acted upon solely by the position of the meter—thus, if the meter be horizontal, the gas passes freely through; but if inclined, the gas is immediately shut off until the meter be replaced in its former horizontal position. The gas, after passing the two valves, enters a chamber, into which the supply pipes to the drum or measuring wheel and the curved gas-holder are inserted. The

HARVEY'S BORING MACHINERY.

FIG. 1.

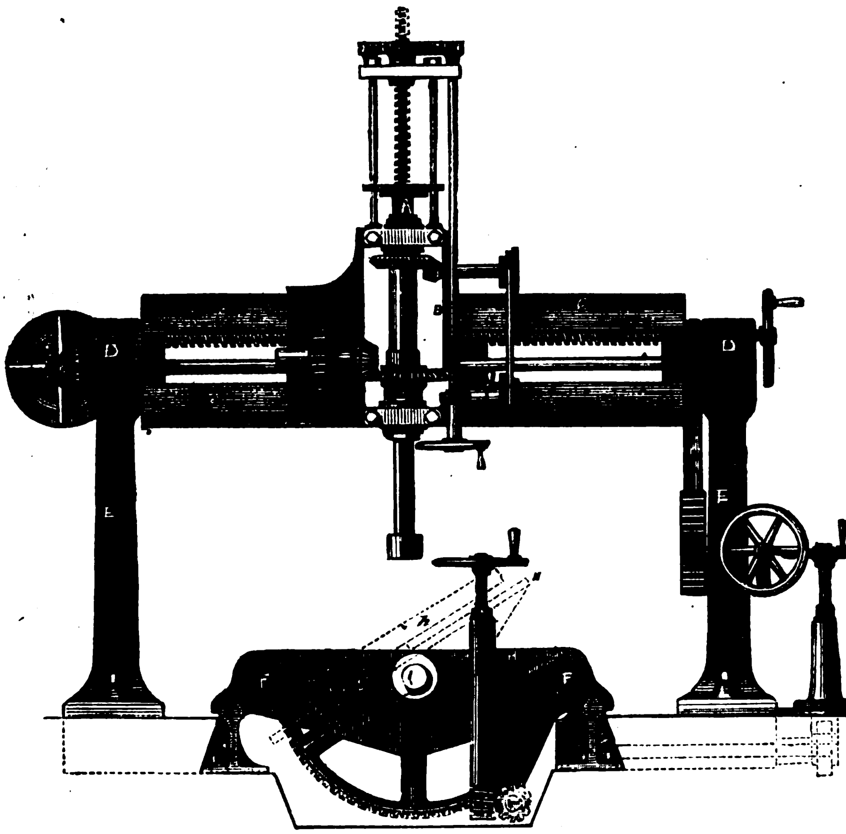

FIG. 2.

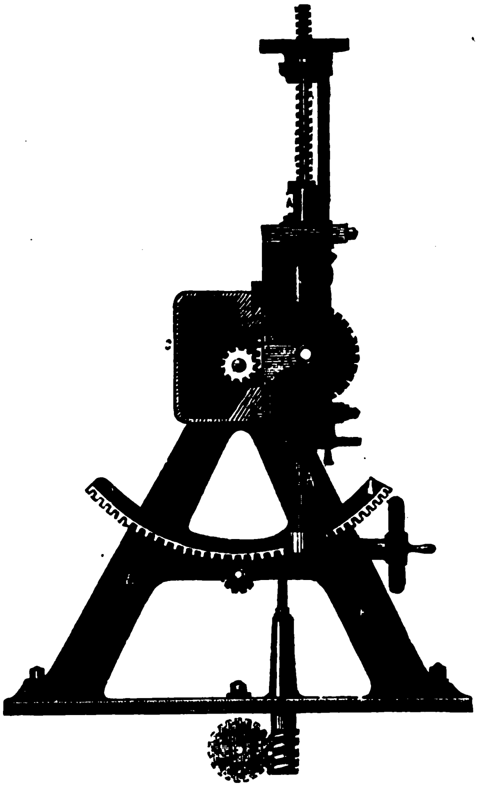

shaft or axis of the drum or measuring wheel is fitted with a worm, by which means motion is carried to the index or registering apparatus through a long toothed pinion fixed to a spindle placed at right angles with the shaft or axis of the drum; provision is made in the long pinion attached to the index spindle for the arc described by the worm attached to the axis of the drum, by cutting the teeth of the pinion of the same radius as that caused by the drum rising and falling, thus the worm presses equally and directly on the teeth of the pinion. Motion is thus carried into the registering apparatus, which is of the ordinary kind.

Fig. 1 of the annexed engravings is a front elevation, partly in section; and fig. 2 is a side elevation, also partly in section, of a gas-meter constructed according to this invention.

A is the drum or measuring wheel, upon the periphery of which is constructed the annular ring or air-tight vessel B. The shafts or axes C, C, of the drum A pass through and are guided by the rectangular frame or double lever D, D, upon one end of which is attached the curved gas-holder F, and on the other end the weight G, or equipoise of the curved gas-holder. E, E, are the points or pivots upon which the frame D, D, vibrates. The meter is charged with water at the plug Q, and passing down the pipe, enters, and filling, the case, buoys up the annular float B and the drum or measuring wheel A. The highest water level S, S, is fixed and determined by the water rising up the pipe *a* and overflowing at the opening *b* through the pipe *c* into the waste water box L, from whence it is allowed to run off by the pipe T. The float J begins to rise when the water arrives at the level W, W, carrying with it the inlet valve I, to which it is attached by the wire as shown, passing through the float J. The gas enters at the inlet union *d*, and passing down the pipe, enters the valve box (the passage of the gas is indicated by the arrows), passing the valve I, into the second valve box and through its valve K, which, being suspended, is effected only by the position of the meter, that is, should the meter be inclined to the back, the valve falls upon its seat and effectually prevents gas from passing until the meter be replaced in its former horizontal position. The gas then passes down the pipe *c* into the waste box L, thence passing up the pipe M to the curved gas-holder F, and up the pipe H into the drum or measuring wheel A, through which the gas passes measured to the outlet union U. The passage of the gas through the drum A causing it to rotate, transmits motion to the index apparatus through the worm N, which is fixed on the axis of the drum and the pinion P, to which is attached the upright spindle V. The index is acted upon bp the spindle V in the ordinary manner. The variation of the water level has no effect upon the registration, as the drum or measuring wheel A in following the water mantains always the correct level in the interior of the drum. The water falling to the level W, W, brings the float J down, thus closing the valve I, and effectually preventing the passage of the gas through the meter.

HARVEY'S PATENT BORING MACHINERY.

A PATENT has been obtained by Messrs. G. and A. Harvey, of Glasgow, for an improved arrangement of machinery for boring holes either in flat or curved plates. Fig. 1 of the annexed engravings is a front elevation of the machinery, and fig. 2 is a side elevation partly in vertical section. In this arrangement the boring spindle A and its driving and feeding details are fitted upon a slide or carriage B, capable of adjustment transversely upon a horizontal guide piece C by means of a screw spindle and hand wheel. The guide piece C is formed with journals at the ends, fitted to turn in bearings D upon standards E bolted to the foundation, and is provided with adjusting mechanism whereby the boring spindle may be inclined to any convenient degree from the vertical in what may be termed the backward and forward direction. The adjusting arrangements consist of a toothed sector fixed on one end of the guide piece C inside the standard E, and in gear with a pinion on a spindle turning in a bearing formed through the standard. On the other end of the spindle there is a worm wheel which is actuated by a worm on the spindle of a hand wheel. To receive and hold the plate or other article there is provided a slide or carriage F, capable of adjustment backwards or forwards upon horizontal guide rails G, arranged below and at right angles to the inclinable guide piece C, and strongly bolted to the foundation. To adjust the slide F backwards or forwards, there is fixed to it at one side a rack with which there gears a pinion on a horizontal shaft (indicated by dotted lines in fig. 1), and this shaft has fast on its other end a worm wheel actuated by a worm on the lower end of a vertical spindle fitted with a hand wheel at its top end. The plate or other article is fixed upon a table indicated by dotted lines at H, and formed with journals I to turn in bearings in the frame of the slide or carriage F. This table H is fitted with adjusting mechanism, whereby the plate or other article upon it may be set at any convenient inclination, but in a direction at right-angles to the direction in which the boring spindle A can be inclined. The adjusting mechanism consists, in this example, of a toothed sector fixed to the table H, and there gears with this sector a pinion on a short spindle carried by the frame F, the spindle having also fast on it a worm wheel actuated by a worm on the lower end of a vertical spindle fitted with a hand wheel. With these arrangements, after the plate or other article has been fixed upon its table or carriage H, it may with the greatest facility be moved by means of the various adjusting mechanism, hereinbefore described, into every position required for boring the holes in it, whatever may be the inclination or direction to be given to the holes within the range of inclination for which the machine is constructed.

The arrangements for driving the drill spindle A may be varied, but those shown in the engraving are simple and convenient—a cross shaft, carrying a driving pulley and a bevel pinion in gear with another wheel on a horizontal shaft placed in bearings in the journals of the inclinable guide piece C so as to lie in the axis of this guide piece; this shaft is fitted with a feather and pinion, which, by flanges on the inside of the slide B, is made to accompany this slide, so as to be always in gear with a spur wheel upon a short spindle carried by the slide. On the spindle of the spur wheel there is a bevel pinion in gear with a bevel wheel on the tubular spindle, which is mounted in upper and lower bearings on the slide B, and has the drill spindle A passing through it, being driven by a groove and feather, which admits of the requisite movement. The drill spindle A is moved or fed downwards by a screw spindle, formed with a cross-head on its lower end and guided upon a pair of rods. A cross-head is fixed on the top of the rods, and carries a spur wheel, through which the screwed spindle passes, which is, in consequence, raised or lowered by turning the wheel. The spur wheel is turned by a pinion fixed on the top of a spindle carried by the slide, and having a hand wheel on its lower end for adjusting by hand. Self-acting feeding gear is also added, there being on the spindle a worm wheel, actuated by a worm on a spindle fitted with stepped pulleys, to be driven by a belt from similar pulleys on a spindle carried by the slide and driven by a bevel pinion in gear with a bevel wheel on the tubular spindle.

ABRIDGMENTS OF SPECIFICATIONS.

An important reduction in the prices of the abridgments of specifications of patented invention has just taken place. We have great pleasure in announcing the new list of prices to enable inventors and others interested to compare them with the former list.

These books are of 12mo size, and as each is limited to inventions of one class only, they can be sold at prices sufficiently moderate to enable the humblest inventor to examine for himself whether his discovery has been previously patented or not.

At the foot of each abstract are given reference to notices of the inventions in scientific and other works, and to the reports of law proceedings for infringements, &c. &c. &c.

The classes already published are,—

Sat. — *Royal Soc.*—"On Electric Telegraphy," by Prof. W. Thompson, at 3 p.m.

Miscellanea.

At the late session of Congress, U.S., an act was passed for the formation of a National Academy of Sciences, and 50 corporators, mostly members of the American Association for the Advancement of Science, were included in the bill. A preliminary meeting of the corporators was held, and 50 members were present, Professor Joseph Henry, of the Smithsonian Institute, was chosen president. A committee was appointed to report a plan of organization for the Academy.

An ingenious German mechanic in Washington, U.S., has nearly perfected a new telegraph instrument, which is on an entirely different principle from those now in use, and may prove far superior to any of them. He is aided by two wealthy newspaper proprietors, who supply him with ample means for making his experiments.

Mr. James Chalmers in a letter says:—Sir,—As the comparative weights of the "Warrior" target and mine have been misunderstood, perhaps you will permit me to state the weight of the former, as given by the Special Committee on Iron —viz., 32 tons 9 cwt. 3 qrs. This gives for an area of 200 ft., after deducting a porthole 3ft. 4 in. by 2 ft., 376½ lb. per foot nearly. The weight of my target, as calculated for the Admiralty by the Engineer Department, is 371½ lb., or 5 lb. less than the weight of the standard target, as given by the committee. This, however, was found to be incorrect, the correct weight being 346·8 or 347, as in the account of the trial of my target in *The Times* of the 27th ult. I was not aware of the error in the weight of the "Warrior" target till it was too late to alter my plan, but, as it had been the criterion for subsequent targets, the committee frankly stated that I was justified in taking it for mine. The plan is now before the Admiralty, with such alterations as will bring it within the standard weight, and probably increase its powers of resistance, as compared with my first target, 25 or 30 per cent.

It was announced at the last meeting of the Institution of Civil Engineers, that the President's annual *conversazione* would be held on Tuesday evening, June 2nd, when the co-operation of members and visitors was requested, in order that a collection of models of engineering construction, and of specimens of works of art, worthy of the Institution, might be made.

The following circular has been forwarded to us:—3, Leadenhall-street, London, 1863.—I am requested to inform you that Mr. Robert Armstrong, C.E., the author of a Treatise on Steam Boilers, and other works and contributions to engineering literature, has, in consequence of accidents which he met with some months since, and also recently, which induced lameness and general debility, been incapacitated from following his usual avocations, and is thereby placed in circumstances of difficulty and distress. It has, in consequence, been resolved by a few of Mr. Armstrong's friends, to endeavour to extricate him from his painful position, and to assist him at his advanced age (69) by raising a small fund for the purpose of placing him in some line of business, or otherwise, by which he may obtain a livelihood. With this view, they solicit your cooperation by contributions and suggestions as to the course to be pursued, and earnestly invite you to associate yourselves with them in acting as a committee for the promotion of the object they have in view. Reference is kindly permitted to be made to Wm. Langdon, Esq., 18, London-street; John Mathewson, Esq., 138, Leadenhall-street; Daniel Kinnear Clark, Esq., 11, Adam-street, Adelphi; Wm. Humber, Esq., C.E., 20, Abingdon-street, Westminster; Benjamin Fothergill, Esq., C.E., 65, Cannon-street, E.C.; Thos. Wright, Esq., C.E., 9, George-yard, Lombard-street; and also to Messrs. W. E. Corner and Son, 83, Gracechurch-street, London.—I am, yours faithfully, Matthew A. Soul. Subscriptions have already been received from:—

and several other firms and gentlemen.

Curious Model of Naval Architecture.—An interesting work of art was on Wednesday on view in the Exchange News-room, Liverpool. It is a correct model, executed in ivory, of the "St. George" line-of-battle ship, of 120 guns, built, planked, and copper-fastened throughout, with all the masts, yards, &c., complete. The model was made expressly for the late Duke of Buckingham, and the period occupied by the artisan in completing his tedious and difficult task was about two years. The antique build of the "St. George" contrasts strikingly with our modern clipper ships.

The Inventors' Institute.—The first annual general meeting of this society took place on Thursday, the 14th inst., at 9, Conduit-street, Regent-street, London. The meeting was numerously attended. Amongst those present were General Sir John Scott Lillie, C.B., Admiral Sir E. Belcher, C.B.; F. B. Beamish, Esq., M.P.; Sir Patrick O'Brien, M.P.; Dr. Normandy; Captain Selwyn, R.N.; Captain Rodgers, R.N.; Mr. Robert Richardson, C.E.; Mr. Benjamin Burliegh; Mr. C. Varley, &c. General Sir John Scott Lillie occupied the chair. A report was read by the honorary secretary, who also read the audited statement of accounts, from which it appeared that after defraying the expenses of the past year and also those incidental to the formation of the Institute there remained a balance in favour of the Institute of upwards of £90. The report and accounts were unanimously adopted, and the council was unanimously re-elected for the ensuing year. After the proceedings of the general meeting had terminated, several of the members adjourned to St. James's-hall to partake of the first anniversary dinner of the Institute. The Earl of Caithness, a vice-president, was unavoidably prevented from occupying the chair, but his place was filled by Lord Richard Grosvenor, M.P., also a vice-president. About seventy gentlemen were present at the dinner, after which the various toasts were replied to by the following gentlemen—viz., General Sir John Scott Lillie, C.B., Captain Rodgers, R.N., William Henry Barlow, Esq., C.E., F.R.S., Hume Williams, Esq., Sir P. O'Brien, M.P., Thomas Webster, Esq., F.R.S., Robert Richardson, Esq., C.E., &c.

Big Ships and Cannon.—Mr. James Bruce in a letter says:—The first ship seen in Greece, arrived at Rhodes, A.D. 1485—Hiero's ship, which was built under the direction of Archimedes, had wood enough employed in it to make gallies to the number of sixty. It had all the varieties of apartments of a palace—banqueting rooms, galleries, gardens, fishponds, stables, mills, baths, a temple of Venus, &c. It was encompassed with an iron rampart and eight towers, with walls and bulwarks furnished with machines of war, particularly one which threw a stone of 300 pounds, or a dart twelve cubits long, the space of half a mile, &c. This ship has been described by Athenæus, the mathematician, who wrote a Greek treatise "On Machines of War." Mahommed II., at the siege of Constantinople, A.D. 1453, used 800-pounders. In 1807, when Sir J. Duckworth passed the Dardanelles, his fleet was dreadfully shattered by the immense shot! The "Royal George," of 110 guns, was nearly sunk by one shot, which carried away her cutwater, and cut the mainmast of the "Windsor Castle" nearly in two; one single shot knocked two ports of the "Thunderer" into one. The "Repulse," 74 guns, had her wheel shot away, and 24 men killed and wounded by a single shot, nor was the ship saved by the most wonderful exertions. These shot were of granite, and weighed 800 lb., and were 2 ft. and 2 in. in diameter. One of these huge shot stove in the larboard bow of the "Actiæ," and having then crushed the immense mass of timber, the shot rolled ponderously aft, and brought up abreast the main hatchway. One of these guns was cast in brass in the reign of Amurath, it was composed of two parts, joined by a screw at the chamber, its breach resting against massive stone work. Baron de Trott resolved to fire this gun, the shot weighing 1,100 lb., and he loaded it with 330 pounds of powder. He says, "I felt a shock like an earthquake, at the distance of 800 fathoms."

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the Mechanics' Magazine at the rate of 6d. per line, or 5½d per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisments.

All communications should be addressed to the Editor, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

AN ATLANTIC TELEGRAPH.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—Resuming my answers to the objections to surface telegraphy stated by Captain Selwyn, I have to remark, as regards the objection that icebergs would come into collision with the cable, that there is nothing to warrant any such conclusion. For, as to the northern route, there are admittedly no icebergs from Scotland to Iceland. From Iceland to near Cape Farewell there also none. Near and at Cape Farewell it would appear there are none; for Sir Edward Belcher, in his evidence (Report on Submarine Cables, page 244, question 4,281), says:—"The heavy ice never presses upon Cape Farewell, and never has been known to touch the southern part of that land at all." Besides, the cable, it will be recollected, will, where it approaches land, always be laid at the bottom, thus obviating Captain Selwyn's objection. Then from Cape Farewell to near Newfoundland, there are, so far as I can ascertain, no icebergs. At Newfoundland they are to be encountered at the season when they come from the Labrador shore along the coast of Newfoundland. But the cable would of course be laid there, as elsewhere on approaching land, at the bottom, thus again obviating the Captain's objection. It may be remarked that the icebergs in Davis's Straits, and in the Atlantic, between Greenland, Labrador, and Newfoundland, are driven and kept to the westward towards and upon the Labrador shore, by the prevalence of the north-easterly winds in that region in the spring months, and it is only when that wind ceases that they float along Newfoundland. And this is the reason why, by adopting the easterly path above pointed out for the cable (easterly as regards Labrador), it would be free from all real danger from ice—as free as the southern cable was, and is, held to have been—and we are all aware that it was not ice that made that cable fail, and that no danger from ice was ever seriously apprehended with reference to it.

Now this conclusion as to the entire safety of the northern cable laid, as proposed, is arrived at, even though icebergs were fully as formidable as they have been generally represented to be. But, after all, do we really know, with scientific accuracy, based upon actual observation, anything sufficiently reliable to warrant the conclusions generally held at present as to icebergs—the exact nature of the ice of which they are formed, their shape, their dimensions, and particularly their depth in the water? It is believed that all these points have been much misunderstood and greatly exaggerated. In conclusive proof of this, we find Sir Edward Belcher, whose experience is beyond all question, saying (p. 245, q. 4,316):—"The greatest measured height of any iceberg that I ever saw was 150 ft., as a pinnacle, and when it canted or turned bottom upwards, it was not above 80 ft." But his letter at page 250 is still more instructive, and on account of its importance I beg to be allowed to quote the following paragraph in full:—"And with regard to the action of bergs on the bottom, and their flotation, notwithstanding experiment on small masses, we certainly witness instances, where we find them *aground, totally at variance with calculation* as regards specific gravity. Two occurred in our last expedition. The first was off the Port of Lievely (Disko), where the 'Pioneer' lost her mizenmast, by falling foul of one aground in 16 fathoms. If the calculated height above water was taken into consideration that berg should have been immersed 800 ft., and yet it was aground in 96, and, further, moved away in 24 hours!" He also mentions another:—"A very large berg, aground in Freshwater Bay, outside the Port (St. John's), from which we obtained fresh water, and at which the boat's guns were fired to shake it. Its outer edge was in six fathoms, its summit about 40 ft. above the sea level." These, and the other facts stated in Sir Edward's Letter, prove that when icebergs are brought under actual and close examination, their supposed extremely huge dimensions *and great depth in the water*, dwindle away to something extremely moderate indeed—to a depth, in short, no way calculated to impede surface telegraphy in the very least degree. Captain Selwyn will thus see that his objection, based on icebergs, is altogether untenable on every ground.

Captain Selwyn again refers to "catenarian strain" as an objection to surface telegraphy. But he must be quite well aware that a wire rope could easily overcome all difficulty, with reference to the mooring of the buoys; and he should, therefore, abstain from further urging this as an objection.

He also refers to "barnacles" as an objection, founding on what "An Old Sailor" says. But my answer to the latter shows that this is no objection at all.

He also says, "I thought, I confess, that when it had been shown that a plan for laying cables near the surface failed in doing more than supporting it at some few points, the idea would be given up." Has the Captain himself ever tried the experiments, on which he bases this assertion and objection? When I did so in one of the ratios mentioned by him, and also in a much greater, I found that he was quite wrong in what he asserted, and that his objection was therefore very ill-founded. It may be necessary, however, for another reason than that assigned by him, to have more buoys. But now that deep sea bottom telegraph cables have failed so often, and are so objectionable on every ground from their position, and are therefore so certain to fail in future, the first point is, not so much, *how many* buoys would be required for a surface cable, but can we get a permanently working telegraph to America by means of buoys, though, in place of six, sixteen, or twice sixteen, were required? In any of these cases, the expense of the buoys, wire ropes, and anchors would be a perfect bagatelle compared to the whole expense and to the certainty of the successful working of the cable, the ample pecuniary return, and all the other great objects in view. It may be here remarked that there can be no real doubt that, judging from the way and length it worked, the cable from Valentia to Newfoundland was a good and sufficient cable, notwithstanding the objections (the most if not all of them imaginary) urged against it, in consequence of its failure; but the simple truth, no doubt, was and is, that it was *gradually* extinguished by the altogether overpowering disadvantages of its position; and such will also be the fate of every other cable, laid at the same depth, combined with so long a stretch, or even much less. But if we place the cable near the surface, every disadvantage disappears, and success is therefore certain.

With reference to what "An Old Sailor" alleged—that the nature of the bottom on which a cable is laid did not signify, I forgot to remind him, in addition to what I formerly said, that volcanic action sometimes takes place at the bottom of the sea, and that surface telegraphy would, of course, greatly diminish the risk to the cable of any evil influences from such a cause.

I may further mention, that I find I conceded too much to "An Old Sailor," in answering the objection, founded on "the insuperable difficulty" alleged by him in ascertaining the depth to within the number of fathoms I propose to submerge the buoys. According to Commander Dayman's clear and most authoritative statement (Report, p. 182, q. 3,110 to 3,116), there is no insuperable difficulty whatever in coming to an exact result as to the depth. It seems to be quite easily accomplished by the Commander's method.

In conclusion. If my plan seems to involve some trouble in its execution, I have yet to learn that anything truly good and great can be attained without due trouble; and it must be recollected that when a telegraph to America shall be achieved, and shall be working permanently, it will perhaps be regarded as the brightest and most consummate fruit of man's genius and invention; and it may, therefore, be most reasonably expected to require the fitting and ennobling exercise of his mechanical skill and power of adaptation to attain the end in view. But, on the other hand, it seems to me to be equally plain that there is no difficulty about its attainment in the mode proposed, entitled, in the very least degree, to the name of insuperable; that there is no difficulty in its attainment that the capital and mechanical skill of Great Britain could not overcome with the greatest ease, and at comparatively little cost if surface telegraphy is adopted, but not otherwise.

I beg to repeat the expression of my obligation to both Captain Selwyn and "An Old Sailor" for the trouble they have taken in the matter, and for the great kindness they have done me in stating their objections. New ideas, however valuable, have, generally, very much to contend against, and neglect is worst of all. But the facts and arguments, *pro* and *con*, in the present case, are now somewhat fully before your readers, subject to further remark or explanation that may seem necessary on either side. H. K.

Edinburgh, May 16, 1863.

MECHANICAL DEFECTS OF MODERN BOOKS.

Sir,—You will, probably, think that a few words will be of some service as regards certain defects of modern books, which defects may, with some latitude of expression, be termed mechanical ones.

The paper used, for the most part, instead of being crisp and elastic, as is the case with that composing many old books, particularly those of a scientific character, is flabby, and has the very disagreeable property of becoming creased by almost the slightest flexure, while its (generally speaking) unnecessary whiteness renders the faintest spots of dirt and stains discernible. And then, again, the ink latterly employed after a few years becomes very perceptibly brown, as clearly appears from the inspection of many works printed less than twenty years ago.

The ancient fashion of printing scientific and other illustrations upon sheets wider than the width of the pages, which fold over, the illustration being contained upon the extra width, by which means the reader could easily consult it when reading *elsewhere*, has, from some unknown cause, been discontinued, I believe universally. This method has several obvious advantages, and should, therefore, be revived.

I am, Sir, yours, &c.,

May 6th, 1863. J. A. Davis.

THE ALKALI MANUFACTURE NUISANCE.

Sir,—Lord Stanley of Alderley has lately introduced a bill into the House of Lords, having for its object, as in Lord Derby's bill of last session, the removal or destruction of the nuisance attending the manufacture of alkali.

Will you permit me, through the medium of your columns, to call the attention of Parliament and the public generally to some facts connected with the provisions of this measure, and to some recent improvements in the manufacture of alkali, which cannot be too generally known. It is proposed by the bill in question to limit the amount of nuisance so produced, by preventing the escape into the atmosphere of more than 5 per cent. of all muriatic acid manufactured, and to enforce this enactment by fine—the proof in each case being derived from the testimony of Government inspectors, who shall have power to enter manufacturing premises at any hour of the day or night.

At first sight it would appear to be a matter of impossibility to ascertain, except by a crude guess, whether 5, or 10, or 15 per cent. of this gas escaped into the atmosphere. I beg, however, to suggest to the Government a very simple clue, whereby, either in respect to this bill or any other of a similar character, the exact percentage of escape may be ascertained to the greatest nicety. For every 585 tons of common salt decomposed by sulphuric acid in the salt-pans and furnaces, 365 tons of dry muriatic acid are evolved—so that it is only for the product of condensation to be gauged, and its strength tested by the hydrometer, and the absolute percentage of escape is at once manifest.

This test, of course, implies the chemical purity of the salt employed, which may be ascertained by analysis; and it also implies the proper knowledge of the manufacturer, and the successful system of operation adopted by him, which in any legislative enactment of this kind are presumed as indispensable necessities.

But to come to the question of limitation contemplated by the bill—the permissive 5 per cent. Let it not be forgotten that it is a twentieth part of the whole quantity manufactured in Great Britain; that the gas in question is most baneful and destructive to animal and vegetable life; and that this twentieth part constitutes in the aggregate no slight contamination to a healthful atmosphere—no meanly poisonous and pernicious blast.

Taken the estimate so given by Lord Stanley of Alderley (which is rather below than above the mark) that the annual value of the alkali trade in Great Britain is equal two millions sterling—then, at the price of £10 a ton, this amount will represent 200,000 tons. Taking the proportion of pure alkali in the commercial article to be 50 per cent.—this gives 100,000 tons—and from the proportion already given, 62,400 tons of dry muriatic acid are evolved in the manufacture of this quantity—5 per cent of this is equal to 3,120 tons. Can any one not conversant with the manufacture imagine the evil resulting from the liberation of 3,120 tons of dry muriatic acid to commingle annually with the atmosphere of the manufacturing districts? Thirty years ago, when the alkali trade had not reached its present dimensions, and when the salt cake was manufactured in reverberatory furnaces, the whole of the muriatic acid was discharged into the atmosphere; and then, whenever a shaft of any importance reared its head, vegetation was more or less blasted over an aggregate area of several square miles, and what the effect of these emanations must have been and still is upon the human constitution may readily be understood by a very simple experiment. Let any one get a single ounce of the muriatic acid of commerce, and pour an ounce of vitriol upon it. The gas in question will be immediately given off, and will at once satisfy the experimentor of its injurious qualities, and oblige him to escape into a purer atmosphere. So intolerable and continuous a nuisance upon a scale of such magnitude as that involved in practice, became the fertile theme of litigation and compromise between the public and the manufacturers; and shafts of immense height were erected to convey the noxious gas into a higher stratum of the atmosphere; but even these, which can only be regarded as an abatement of the nuisance, were soon found to be insuffisient, and the present arrangements, which are those, no doubt, referred to by Lord Stanley of Alderley, as being able to absorb the principal bulk of the gas, came into operation. They are the invention of Mr. Gossage, and may be briefly described as a series of massive towers constructed of large rectangular slabs of silicious stone, and bound externally by stout iron clamps. They are filled throughout with coke—a small stream of water is allowed to trickle from above downwards, which meets the ascending gas, and in part absorbs it. What is not absorbed of the gas makes its escape into the atmosphere through an underground flue leading to the shaft, which arrangement is adopted in order to create a draught through the apparatus. The muriatic solution so produced is used subsequently to decompose peroxide of manganese for the purpose of producing bleach (hypochlorite of lime or bleaching powder). A far better method of destroying the nuisance, and utilizing the result, is to *imprison the muriatic acid from the atmosphere altogether*, and perform the two consecutive manufactures referred to in a single operation; and this brings me to the improvements adverted to in the beginning of my letter.

A patent has lately been taken by Messrs. Baggs and Simpson, of which the following is a brief summary:—They shut off all communication with the atmosphere, and compel the muriatic acid to enter a close vessel containing water and black oxide of manganese. As the pipe which conveys it dips into the water, it is instantly absorbed, and from the affinity existing between water and muriatic acid, considerable heat is evolved. This heat increases with the absorption, and in a few minutes becomes sufficiently great to decompose the manganese, and yield chlorine gas without the application of any external fire. Every particle of muriatic acid is, by these means, converted into chlorine, as it is evolved. Not a fraction per cent. is permitted to escape into the atmosphere, and the chlorine, as it is produced, is conducted by another pipe into a stone cistern containing lime and water, or into a leaden chamber containing hydrate of lime, where it is simultaneously converted either into a solution of bleach or into solid chloride of lime, according to the apparatus employed.

I have thought it better to give publicity to these facts while yet the bill is before Parliament; for in a measure so closely affecting the health of the public, and, I may also add, the economy of manufacture, I consider it not only behoves, but is the anxious wish of, the Legislature to have their prohibitory enactments relative to the correction of this serious nuisance upon the extreme susceptibilities of real and practical prevention as developed by the most modern discoveries.

I am, &c. ARGUS.

A PATENT GRIEVANCE.

SIR,—I am the victim of a grievance for which I do not see a remedy. I am an inventor, and, as a matter of course, a poor man. I have, however, hit upon an invention which I fancy will greatly improve my position—all inventors, you know, are sanguine. I have raised money enough to apply for a patent, hoping that, within the *six months* for which provisional protection is supposed to be granted, I shall be able to demonstrate the value of my invention, and so obtain assistance to proceed. I cannot, of course, try or perfect my invention until it is protected; and I now find, to my sorrow, that instead of the professed protection for *six* months, I shall probably not get *three!*

Upon filing my application for a patent, it was referred (being an odd number) to Her Majesty's Attorney-General, who is such a slow coach that, although just six weeks have elapsed, I have not yet received provisional protection. This officer is nearly two hundred patents in arrear of his brother Commissioner (for the even numbers) the Solicitor-General, who turns out his work in business-like style. Now, by the time I get Provisional Protection, give notice to proceed, and get my patent out of purgatory (risk of opposition), half the period of protection will be gone, and I shall probably break down.

If Mr. Attorney-General is unwilling or unable to do his duty, could he not turn one-half of it over to the Solicitor-General, who is two to one a better man for this kind of work? It is of no use going and complaining to Mr. Attorney's clerk, for I should only get put back, annoyed in all manner of legal ways, and perhaps be refused a patent. Like Archimedes of old (who could have moved the world) I could move the Attorney-General but for want of a fulcrum!

I remain, Sir, your obedient servant,
London, May 15, 1863. A LEVER.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c., 2861, 2884, 2890,
BOILERS AND FURNACES, 2867, 2885.
SHIPS AND BOATS, including their fittings, 2857, 2864.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2870, 2874.
CULTIVATION OF THE SOIL, including agricultural implements and machines, 2888.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 2853, 2854, 2887, 2891.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2866, 2880.
BUILDINGS AND BUILDING MATERIALS, 2863, 2893, 2898.
LIGHTING, HEATING, AND VENTILATING, 2851, 2869, 2873, 2877, 2883.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2855, 2868, 2871, 2878, 2879, 2886, 2889.
METALS, including apparatus for their manufacture, 2859, 2872.
CHEMISTRY AND PHOTOGRAPHY, 2856, 2881, 2882, 2894, 2895.
ELECTRICAL APPARATUS—*none.*
WARFARE, 2875, 2897.
LETTER-PRESS PRINTING—*none.*
MISCELLANEOUS, 2852, 2858, 2860, 2862, 2865, 2876, 2892, 2896.

2851. J. T. STROUD. *Improvements in lamps for general and special purposes, and in parts connected with the same.* Dated October 23, 1862.

This invention has reference to a previous patent, dated July 28, 1862, No. 2140, and consists, under one modification, in supplying moderator lamps with oil or fluid for supporting combustion through a supply pipe conveniently placed at the top, having a plug fitted to the same, and which plug the patentee makes hollow, for the purpose of introducing a float consisting of a cork, or other light suitable material, attached to a small vertical wire, which passes through a cross-piece in the neck of the tube for receiving the plug before mentioned, allowing the float to rise when full. The details are voluminous. *Patent completed.*

2852. W. S. GAMBLE. *An improved salinometer.* Dated October 23, 1862.

This invention is carried out in practice as follows:—Within a metal case the patentee adapts a large glass tube, the lower edge of which rests on a flange, to which it is fixed water-tight, the upper edge of the said tube being held in position water-tight by means of a short hollow casting, and a screw cap tightening thereonto. The aforesaid metal case is made as a double cylinder, or two cylinders one within the other, the outermost cylinder having a long opening therein for reading off the indications of a hydrometer placed within the aforesaid glass tube. An important feature of this invention consists in forming the bulb of the hydrometer with points around and about its largest diameter, the scale of the salinometer being so adjusted to read off from the bulb of the hydrometer, instead of from the surface of the water, as heretofore practised. Another feature of this invention consists in employing a three-way cock, instead of two separate cocks, as ordinarily practised; by these means the operation of blowing may be performed direct through the three-way cock aforesaid, instead of blowing through the salinometer, as heretofore practised. He also proposes to adapt a piece of wire gauze to the bottom of the large glass tube containing the hydrometer, and by placing a cap on the top of the salinometer, ebullition of the water is almost entirely obviated, and the water is thus kept clear, by which the reading of the scale may be more readily and accurately accomplished than by the use of salinometers as heretofore constructed. He proposes to adopt a thermometer within the salinometer visible from the outside. He also proposes to adapt a small valve with a fine thread or screw cut about its stem for adjusting the extent of the opening of the induction passage of the three-way cock aforesaid, leading from the steam boiler into the salinometer, an eduction passage being formed within the case of the salinometer, extending from the top to the bottom thereof to carry off the water into the waste pipe. *Patent completed.*

2853. A. CHAPLIN and G. RUSSELL. *Improvements in obtaining fresh water by evaporation, and in apparatus therefor.* Dated October 23, 1862.

This invention consists in employing what may be termed the "jet" action of the steam when passing towards or into the condensing worm or other condenser, to draw in and thoroughly intermingle with itself sufficient atmospheric air to combine with the water of condensation, and impart to it the well known "fresh" character which distinguishes spring water from ordinary distilled water. *Patent completed.*

2854. J. TURNBULL. *Improvements in mills for grinding grain.* Dated October 23, 1862.

This invention relates to that class of mills for grinding grain known as vertical mills; that is to say, the bed or stationary stone is placed on its edge, and the grinding surface therefore in a vertical position, while the running stone is mounted on a horizontal axis, its face being brought up parallel to the face of the bed-stone. The patentee places the bed-stone to about half its thickness into a cast-iron box or case, which encircles and fits it somewhat closely, and bolts fixed with lead on the stone project through the holes in the disc of the case, over which are mounted bridge pieces fixed on the case; the screw parts of the bolts pass freely through these bridge pieces, and are held by nuts on each side of such bridge frames, by which means the position of the bed-stone can be adjusted at will. The shaft on which the patentee mounts the running stone passes quite through the bed-stone, and is supported at that end by a bearing formed in a cast-iron boss fitted in the eye of the stone; or the shaft may pass freely through the end of such boss, and be supported by an independent bearing. The boss fitted in the eye of the bed-stone is cylindrical, and considerably larger than the shaft which occupies the centre, in order to receive an archimedian screw, which carries the feed through the bed-stone, and up to the face of the running stone. The screw is fixed on the shaft, and therefore rotates with it. The feed is delivered by a spout into a small hopper or shoot made on the back end of the boss, which conducts it to that end of the screw. The cylindrical boss is bolted to the case receiving the bed-stone. The hopper receiving the grain in bulk is in suitable position, and has a slide to regulate the passage of the grain, which passes from thence by a spout or shoot to the boss hopper before mentioned. This shoot is fitted with what the patentee terms a spring bottom, being a sheet of metal by which the upper end is attached; it is suspended towards the other end by a rod furnished with a regulating screw and nut. Immediately below the shoot bottom, he mounts a tappet piece on the stone shaft, which projects through the stone boss, as before mentioned. The tappet has two, three, or more points of contact which strike the bottom of the shoot, and cause the grain to pass regularly down the shoot, whereby a regular supply of grain to the stone is ensured. *Patent completed.*

2855. W. CLARK. *Improvements in sewing machines.* (A communication.) Dated October 23, 1862.

This invention consists, in part, of a novel mode of controlling the needle thread of the sewing machine, whereby the quantity delivered to the needle is caused to be always in proportion to the thickness of the cloth or other material being sewed, and the length of the stitches to be made, and a uniform tightnness of stitch is produced, whatever variation may occur in the thickness of the material, or however the feed motion may be varied, obviating entirely the necessity of any manual adjustment by the operator for sewing material of different thickness. It also consists in an improved mode of applying the locking thread spool or bobbin in combination with the rotating hook of what is known as the "rotating hook sewing machine," whereby a much larger bobbin or spool can be used than by the modes of construction heretofore adopted. Also in a loop check of novel construction, operating to check the loops of the needle thread in their passage over the rotating hook without aid from any other part of the machine, and serving also to hold in position a spool case which contains the locking thread. Also in certain improvements in the feeding device, whereby it is better adapted to the feeding of work of varying thickness, and made to work with little noise. And it further consists in certain improvements in the construction of the thread spools for containing or carrying the thread used, or to be used, in sewing machines, whereby they are made to occupy very little room, and to contain a large quantity of thread in a very small compass, one object of this improvement being to have the thread spooled by the manufacturer in a form suitable for use as the locking or lower thread in the rotating hook sewing machine without the necessity of rewinding or respooling. *Patent completed.*

2856. E. Bath. *Improvements in treating alkali waste to obtain sulphur therefrom.* Dated October 23, 1862.

The principle on which this process is based is the mutual decomposition which takes place when sulphurous acid gas and sulphuretted hydrogen are brought into contact, water being formed and sulphur being precipitated. The operation is conducted as follows:—The sulphurous acid is produced by the calcination in muffle calciners of either copper or iron pyrites or coarse regulus, or by the burning of sulphur. The sulphuretted hydrogen is produced from the waste products of alkali manufacture, viz., alkali waste and hydrochloric acid; by the addition of the latter to the former sulphuretted hydrogen is evolved, and chloride of calcium remains in solution. The two gases, viz., sulphurous acid and sulphuretted hydrogen are caused to enter at the bottom of a tower filled with round smooth pebbles, through which water is caused to percolate, the two gases on meeting are decomposed, and sulphur is precipitated in a finely-divided state. The action of the water is as follows:—By its means the tower is kept at a low temperature, and the finely-divided sulphur as formed is brought out, and thus the tower is kept in a continuous working state, and clogging is prevented, without the necessity of stopping the process to remove the accumulated sulphur. The water also acts as a sort of reciprocating balance between the two gases, as whichever may be in excess for a time is absorbed by the water and retained until the just combining proportions of the two gases are restored by the workman. The water also furnishes an index of the proper working of the process, as whichever gas may be in excess is apparent at once by the smell of the water. *Patent abandoned.*

2857. M. C. A. Perkes. *An equilibrium double action revolving rudder, self-balancing drag, and improved steering gear.* (A communication.) Dated October 23, 1862.

In carrying out this invention, the inventor constructs the rudders of double their ordinary widths, and inserts the rudder post in the middle, which thus forms a central shaft or axis, on which the double bladed rudder is made to revolve when in use. The foot of this central shaft is supported on proper bearings from the keel, and the stern of the ship is slightly undercut or recessed, so as to receive the rudder and allow it freely to revolve as described. The upper portion of the central shaft is continued through a well hole to the deck in the ordinary way, and supported by proper bearings made portable, by preference, so as to be capable of immediate removal for any required purpose. On the top of this shaft is fixed a horizontal spur wheel, which is set in motion by a suitable pinion, and which pinion is attached to the foot of a vertical shaft, rotating in a suitable frame, which is fixed on the ship's deck for the purpose of supporting the steering wheel. He prefers to use the steering wheel horizontally for giving motion to the rudder, but a vertical steering wheel can be applied, by using mitre or bevel gearing to convey the motion to the rudder whenever required. On the upper side of the horizontal tiller wheel, as fixed on the top of the rudder post, he provides an indicator of similar form to the rudder, and paints it some conspicuous colour with points exactly to correspond with its direction, so that the true position of the rudder can always be seen on deck. The steering wheel he also provides with one or more suitable fastenings, so that it may be instantaneously and securely locked in any required position. *Patent completed.*

2858. H. Rek. *Improvements in apparatus for exercising the human body.* Dated October 23, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2859. H. Donald. *Improvements in machinery or apparatus for bending or straightening metal plates.* Dated October 23, 1862.

This invention relates to the arrangement and construction of machines or apparatus for bending or straightening the metal plates used in shipbuilding, and for other generally similar purposes. Under one modification, the machine consists of a pair of cast-iron end standards, connected by horizontal tie rods. Each end standard is made with a rectangular opening in it, the vertical faces of which are grooved to receive a sliding block. These blocks carry the bearings of a heavy roller, which, in machines of the ordinary kind, serves as the bending roller, but in this modification it is not used for that purpose. Below this roller is arranged another roller of smaller diameter, which is used for the bending of the plates. This roller being of comparatively small diameter, plates can be circled to a much smaller diameter than can be accomplished with the ordinary bending machines. This improvement is very advantageous for bending mast plates, or other similar forms. The small roller is arranged to work in frictional contact with the upper roller, and this arrangement prevents it springing when bending heavy plates. Below the smaller roller are arranged two other rollers parallel to each other, their peripheries extending out beyond the smaller roller. These rollers are driven by means of suitable gearing, and they serve to guide and carry the plates in either direction under the bending roller. The peripheries of the pair of rollers are indented or grooved longitudinally, one face of the indentation forming a vertical line, whilst the other is bevelled off until it merges into the periphery of the roller. With this arrangement, when a plate is passed into the machine to be bent, its front edge glides into one of the indentations without the noise or shock which takes place when the grooves have two vertical faces, as in the ordinary arrangement. The bending roller is fitted on two moveable brushes, so that by removing these the bending roller is lowered, and its peripheries then rest on the pair of grooved rollers beneath. In this position the bending roller and the upper roller may be used for straightening plates. The distance between the two rollers is regulated by causing the sliding blocks which carry the upper roller to traverse up and down. *Patent abandoned.*

2860. E. H. Carbutt and G. A. Clough. *Improvements in power hammers.* Dated October 23, 1862.

This invention relates to certain improvements in steam hammers, whereby they are rendered self-acting, the length of stroke being adjustable in either direction. According to one method of carrying out this invention, an inclined groove or its equivalent is made to communicate with a bowl sliding in a transverse groove on the hammer frame through a lever of the second order, or any other mechanical expedient by which the patentees can gain their object - namely, giving the inclined groove first referred to very little deviation from the vertical in proportion to its length, and gaining the travel they lose in the incline by the lever or its equivalent in connection with the bowl, which transmits its motion to the valve through wedges made adjustable by screws or levers on a special moveable frame in connection with the valve. One of these wedges has means provided by which its pitch or inclination can be regulated. This adjustment regulates the amount of steam supplied to the cylinder; or the steam can be entirely shut off from the upper side of the piston. The moveable frame admits (as also does the means of gaining travel) of many modifications. By another method, they render steam hammers self-acting by causing the steam actuating the hammers to move the valve directly. According to the second part of the invention, they propose to form steam hammers known as single-action hammers in a peculiar manner. They form the tup cylindrical, and of a diameter in proportion to the size of hammer. Means are provided on the said tup at its upper end for attaching a wrought-iron or any other metal cylinder to it. The annular space thus formed between the tup and the cylinder attached to it is occupied by the main piston, which is a fixture, and is attached to the hammer frame. They also substitute for the present steam valve a pendulous one, where the exhaust passes outside the case or through the valve, while the outside of the valve is surrounded with steam. *Patent completed.*

2861. J. Field. *Improvements in steam engines, condensers, and boilers.* Dated October 23, 1862.

This invention consists—1, in an improved method of adapting a high-pressure cylinder, on Woolf's system, to the ordinary double piston rod arrangement of horizontal steam engines. The inventor places the small or high-pressure cylinder concentric with the large cylinder, and immediately in front of it, between it and the crank shaft, the two piston rods from the large cylinder pass, one on either side of the small one to the crosshead on either side of the crank shaft, with a connecting rod returning to the crank in the ordinary way; the piston of the small cylinder is connected to the large piston by a rod passing through a steam-tight joint between the two cylinders. This arrangement allows of the covers of either of the cylinders being easily taken off when required for examining the pistons and otherwise. 2, The invention consists in an improved form of surface condenser, so as to enable the tubes to be readily inspected and cleaned. He places the condensing tubes in a position inclined from the horizontal line, with covers forming chambers at each end; the exhaust pipe from the cylinder is brought into the chamber at the highest end of the tubes, and the condensed water is delivered into that at the lower end, from which it is conveyed to the air-pump. This arrangement leaves the ends of the tubes conveniently exposed, when the covers are removed so as to be readily cleaned when required. And 3, The invention consists in adapting the ordinary description of tubular boiler with return tubes over the fireplaces for using a higher pressure of steam than can be safely used in a rectangular boiler, however stayed. He places the fireplace, which is cylindrical, inside a cylindrical outer case, and also places another cylindrical case above it of sufficient capacity to contain the requisite number of tubes; these cases are connected together at the back by a chamber which contains the rising flue leading from the fireplace, and which can be stayed in the ordinary manner to bear the requisite pressure. He also forms a water connection at the forward end of outer cases, in order to keep up a proper circulation in the boiler. One or more fireplaces may be placed in the lower cylindrical case leading into one rising flue, as may be most convenient. Any number of these boilers may be placed together and connected so as to be worked together or separately. *Patent completed.*

2862. R. A. Brooman. *Improvements in tanning.* Dated October 23, 1862. (A communication.)

This consists in the employment of pressure to cause the tannin to penetrate into the pores of the hides. The apparatus employed is not described apart from the drawings. *Patent completed.*

2863. A. J. F. V. Beepson. *A syphoidal cistern with water reservoir for kitchen or other drains in communication with infected sewers.* Dated October 24, 1862.

The apparatus or contrivances in use for running off kitchen or other refuse waters in private dwellings or public establishments permit bad smells to escape, or require to be opened when used either with a key or lever, giving, whenever opened, issue to fœtid odours. The syphoidal cistern or trap with water reservoir and hydraulic shutting or closing, the subject of the present invention, is intended to prevent the said inconveniences. It is composed of a basin kept constantly full of water to submersion to its top edge, so that, on pouring any more in, the pressure causes the level to rise, and the overflow takes place through large vent holes or outlets suitably disposed, and the waters run off, leaving the basin always full to the same level as before. This very simple apparatus prevents the rippling of the water when falling from a spout into the basin, and at the same time intercepts any fœtid emanations or efflux. This apparatus can be adapted with suitable modifications of arrangement to any places, such as kitchen drains, kennel gratings, cesspools, or sink holes of drains in which run filthy or infected waters. The basin is hermetically closed at its lower part, and the overplus of water, having no escape hole, cannot run out but by raising its level to the vent holes or purging outlets, which are hermetically closed themselves at their top within the apparatus by a bottomless basin, the lower edge of which dips in a circular drain or groove. The nauseous efflux could not thus penetrate to the places which are to be preserved therefrom, except by running through a deep bed of water, which is not possible. *Patent completed.*

2864. C. C. Burmeister and W. Wain. *Improvements in the construction of cupolas, and in apparatus connected therewith, for naval or other war purposes.* Dated October 24, 1862.

The shield or exposed parts of cupolas for protecting guns and gunners, the inventors prefer to construct entirely of metal, by preference iron or steel, in one or more layers or thicknesses, and of hemispherical form. The shield has a series of ports formed around it, suitable for the muzzle of the gun to pass through, each port being furnished with doors or slides to close or open the same when required: and other port holes may if desired be formed in the shield suitable for hand-rifle firing. The crown of the shield is covered by a perforated metal plate to afford protection and ventilation, and rotary movement is communicated to the shield by suitable mechanism, actuated by hand, steam, or other motive power, the whole being mounted so as to rotate around a central hollow axis. An inverted hollow ring is fixed on the outer circumference of the cupola or shield near its base, which overlaps the vertical rim of another ring fixed on the deck or floor of the battery, in order to prevent the introduction of gunpowder or other explosive or destructive matters. The gun or its platform may be arranged to rotate on a central pin or axis within the shield independently thereof, if desired. *Patent abandoned.*

2865. L. Groux. *Improvements in the manufacture of soap, and in machinery for that purpose.* Dated October 24, 1862.

The patentee claims—1, Mixing plain and coloured soaps, either separately or together, whilst cold, or mixing colouring matters or perfumes therewith whilst the soap is in a cold state. 2, The use of cylinders and pistons for mixing soaps whilst cold, and further, making the outlet pipe at which the soaps are forced out in the form of a star or other shape, as described. 3, Mixing together hot and cold soaps of different colours in vessels as described with reference to the drawing. *Patent completed.*

2866. J. Ginson and R. Flude. *Improvements in looms for weaving narrow fabrics.* Dated October 24, 1862.

This invention relates to those kinds of looms in which the shuttles are thrown either by toothed pinions working in racks, or by what are known as peg motions. The first improvement relates to a novel mode of actuating these drivers, whereby the shuttles are passed through the sheds, and consists in actuating these drivers by means of levers which are vibrated by causing their inner ends to work in a cam groove formed in a barrel, drum, or cylinder mounted on any convenient rotating shaft belonging to the loom. By this means a smoother and less noisy motion is imparted to the drivers than that produced by the use of treadle levers with chains, cords, or bands, as is now generally the case. The next improvement relates to the peg motion, and instead of fixing the pegs immoveably on the drivers, they are made moveable therein in a vertical direction so that they may be moved up and down for the purpose of being inserted into or withdrawn from the holes in the shuttles. *Patent abandoned.*

2867. J. R. Nicholl. *An improved construction of fire-place or stove-grate.* Dated October 24, 1862.

The object of this invention is to supply coals to open fire-places or stove-grates, in such a manner as to economize the consumption of fuel and to check or prevent the formation of smoke. To this end the inventor fits up the fire-place or stove-grate with a sliding back, which may be advanced or pushed back at pleasure, and in front of this back he hangs a swing plate which has a tendency to take an inclined position, and form with the sliding back a kind of temporary hopper or shute. When the fire is burning brightly in the grate, the back will be in an advanced position, and the swing plate will be retained by the sliding back in a vertical position; but when a supply of coals is required, the attendant will thrust the sliding back (by a rod, rack and pinion, chain and pulley, or other convenient means) to its furthest backward position, and thereby leave the swing plate free to take the inclined position. This plate he so shapes, that when inclined and forming with the sliding back as above stated a hopper or shute to receive a charge of coals, an opening will be presented for the coals to descend into the grate at the back of the burning fuel. This being done, the attendant draws forward the sliding back, which, now acting as a plunger, forces the fresh coals under the incandescent fuel in the grate. The gases therefore evolved from the fresh coals will pass through the incandescent fuel and become consumed. *Patent abandoned.*

2868. J. Wright. *Improvements in the construction of seamless stays.* (A communication). Dated October 24, 1862.

The object of this invention is to produce a seamless stay, not only more perfect in form, but formed of materials not only of different colours, but of different compositions, so as to be suited for wearing in different seasons according to the temperature. For this purpose the inventor substitutes for the present materials forming the lining and facings of woven corsets a material of elegant reps, similar to those used in making gobelins designs; from this lining or covering which has the warp removed, he weaves the woof in wool of all sorts of textile materials, and of different colours. *Patent abandoned.*

2869. J. T. Shroud. *Improvements in the manufacture of, and in the machinery and appliances for, holding, drilling, turning, tapping, fitting, and shaping certain parts of steam, water, gas, and lamp fittings.* Dated October 24, 1862.

We cannot here give space to the details of this invention. *Patent abandoned.*

2870. P. S. Devlan. *Improvements in the manufacture of bearings, steps, axle boxes, and other surfaces and appliances or articles subjected to friction.* Dated October 24, 1862.

The object of this invention is to form bearing surfaces and linings, packings, or internal fittings for axle boxes and steps, and to produce other surfaces or articles subjected to friction. For these purposes he uses asbestos, or other mineral fibrous substance, combined with a gummy, glutinous, feculous, or albuminous substance, or other substance capable of rendering it cohesive. *Patent completed.*

2871. G. and W. Luke. *Buckle eye stirrups.* Dated October 25, 1862.

This invention is applicable to all kinds of stirrups, in whatever metal they may be made, and consists in doing away with, or rendering unnecessary, the buckle used with the ordinary stirrup-leather, and substituting for it a moveable tongue or pin of iron, steel, or other metal fitted into, on, or upon the upper or lower bar of the eye or loop in the stirrup itself, so as to provide for the shortening, lengthening, or fastening the stirrup-leather when or as required. *Patent completed.*

2872. J. Carpendale. *Improvements in the means of producing raised chasing on Britannia and other compressible metals.* Dated October 25, 1862.

This invention consists of a mechanical contrivance, by which the mode of producing raised chasing by mere manual pressure, hitherto partially resorted to, is superseded, and the use of steel plates or dies, with the negative of the ornament to be impressed on the metal engraved or cut therein, is made practically available. The first motion from the driving shaft is applied to drums in the usual manner, on the axis of which is fixed a disc of wood or other material, in which the steel plate or die is embedded. Parallel to the face of this disc a slotted guide is placed, in which a block containing the pressing tool is fixed; the block is moved in the slotted guide by a screw with a crank handle, and another screw acts upon the head of the pressing tool. Upon the face of the steel plate, cut or engraved with an appropriate design, the metal to be operated upon is fixed, and the pressing tool screwed upon it with such amount of pressure as may be necessary to produce a true positive impress of the design cut in such plate or die. *Patent completed*

2873. W. Owen. *Improvements in stoves.* Dated October 25, 1862.

This invention relates—1, To what are known as register stoves—viz., such as are furnished with a door opening into the chimney, and it consists in fitting below or in front of such door and independent of it a frame of louvre plates. This frame moves as upon hinges, and is capable of being thrown entirely back to allow of uninterrupted access to the chimney. The invention relates—2, To those stoves known as air stoves, and consists in forming them with radiating chambers instead of with solid plates, as heretofore. *Patent completed.*

2874. G. T. Key. *Fog and other signals.* Dated October 25, 1862.

This invention consists in the application of bellows to sound a wind instrument (such as a foghorn, the horn forming the spout of the bellows), or two or more differently sounding wind instruments (as, for example, a foghorn and whistle) for signalling during fogs and at other times. The bellows may be made either single acting, double acting, or continuous acting. *Patent abandoned.*

2875. D. and W. Brown. *Improvements in rolling machinery for rolling gun barrels, cannons, and other articles.* Dated October 25, 1862.

This invention consists in driving or actuating the rolls of rolling machinery by so constructing and arranging the driving gearing that an intermittent rotary motion is communicated to the rolls, the said rolls being brought to rest at the proper times for the purpose of permitting of the ready introduction of the gun barrel or other article between the rolls. *Patent abandoned.*

2876. J. A. Nicholson. *Improvements in lead, crayon, and other pencils.* Dated October 25, 1862.

This invention consists in forming grooves longitudinally or otherwise from end to end in those articles, for the purpose of removing a considerable portion of the material of which they necessarily consist, in order to render them more easily pointed than when left solid as usual. *Patent completed.*

2877. W. Clark. *An improvement in the construction of the joints of cast-iron gas and water mains, and other pipes.* (A communication.) Dated October 25, 1862.

This invention consists in making such joints by forming grooves or recesses around the interiors of the sockets or larger ends of the pipes, making the smaller ends slightly taper, casting rings of lead or other soft metal or alloy within the aforesaid grooves or recesses before putting the pipes in the ground, or into the places they are to occupy, and afterwards drawing or forcing the taper smaller ends tightly into the aforesaid rings, by which means a tighter, more durable, and more flexible joint is obtained than by the ordinary construction, with a great saving of lead or other soft metal or alloy that may be used, and the pipes are enabled to be laid more expeditiously. *Patent completed.*

2878. A. Clark. *Improvements in the construction of bows and pendants of watches.* Dated October 25, 1862.

In carrying out this invention, the inventor proposes to form the ball of the pendant of the watch in three divisions; the lower division of which is a fixture on the pendant, the central division being a swivel, and the upper division cut with a screw thread, or fixed on to the pendant by hammering or enlarging the head of the latter. The bow of the watch is to be attached to the swivel or central division of the ball by its insertion therein, and by a pin or a nut, or other fastening adjusted thereto. *Patent abandoned.*

2879. P. Alfraise. *Improvements in sewing machines.* Dated October 25, 1862.

This invention relates to sewing machines, both of the shuttle description and other kinds. The first improvement consists in actuating the needle-carrier by a jointed frame or parallelogram, which consists of four jointed or articulated levers, bars, rods, or arms, and acts as the tension piece for giving the tension to the thread. By this arrangement the noisy gearing in present use is dispensed with. The second improvement consists in the employment of a cam or an eccentric, or a round plate or disc, on which is a groove or grooves, or slot or slots, in the form of a volute, for the purpose of actuating the parallelogram or jointed frame. The third improvement consists in combining a pulley or wheel with a stationary eccentric or cam, whereby the inventor obtains the stopping interval of the needle while the shuttle is passing. The fourth improvement, which is applicable to glove-sewing and other descriptions of sewing machines, consists in communicating to the needle-carrier, in addition to its to-and-fro motion, a shifting motion, or motion whereby it shifts or changes its position at each stroke of the needle, in such manner that the stitches come in two rows a short distance apart, the direction of the rows being in parallel right lines, or side by side, but the stitches falling alternately or intermediately. *Patent abandoned.*

2880. T. G. Ghislin. *Improvements in the treatment and utilization of certain foreign plants for the obtaining of useful fibres therefrom.* Dated October 25, 1862.

This invention relates to the obtaining from a class of bulbous plants of the Liliaceous and Amaryllidaceous Orders fibre suitable for spinning into yarn, and for being converted into paper pulp. In order to obtain the fibre suitable for spinning, the patentee takes the ball (if in a fresh state) and boils it in water, or water rendered slightly alkaline, until the resinous matter contained in the plant is dissolved and the bulbs have become soft. The soft pulpy mass thus obtained is then submitted to pressure in a press, in order to expel therefrom the liquid, together with whatever has been dissolved, and he thus obtains the fibre in a matted state. If preferred, the expulsion of the liquid may be effected by means of centrifugal apparatus, as is well-known. He next washes the fibre, and for the purpose of opening it out subjects it to the action of steam at a suitable pressure, after which he dries the fibre by exposure to the air, or in a heated atmosphere. The fibre thus obtained he proposes to card, draw, and spin in the usual way. When the bulb is dry, he strips off the outer cuticle, and, by preference, boils the bulb in an alkaline solution, and he afterwards neutralizes the alkali by weak acid. He next subjects the fibre to a bleaching process, using either gaseous chlorine or chloride of lime, or any other material commonly used for this purpose. He then removes the bleaching agent by washing, and afterwards removes the moisture from the fibre by means of pressure or centrifugal apparatus. He then again washes the fibre in water, opens it out by steam, and drys by exposure, as in the former instance. *Patent completed.*

2881. E. A. L. Negretti and J. W. Zambra. *Improved apparatus for ascertaining or testing the explosibility of liquid hydro-carbon.* (A communication.) Dated October 25, 1862.

This apparatus consists of a thermometer, the bulb of which is made to dip into a cup or vessel in which the hydro-carbon to be tested is placed, and is heated by a spirit lamp or water bath beneath. Upon the hydro-carbon being heated, it will give off vapour in proportion to its volatility and the heat employed, and this vapour, after being allowed to mix with a certain proportion of air in a suitable chamber or vessel, will form an explosive compound. Upon introducing a flame into the chamber or vessel where the mixed gases are, a slight explosion will take place if the proper proportion of gases are there. After the first explosion, the exact time required for evolving a sufficient quantity of vapour to produce a second explosion must be noted, the temperature of the hydro-carbon must also be ascertained by referring to the thermometer. By this means the lowest temperature at which the hydro-carbon will form an explosive compound will be indicated by the thermometer. *Patent abandoned.*

2882. J. P. Bourquin. *An improved manufacture of mount for photographic and other albums, miniatures, and other pictures.* Dated October 25, 1862.

The object of this invention is to manufacture mounts that will not soil with the touch, and which when dirty may be readily cleansed without injury thereto. This the inventor proposes to effect by substituting veneers of choice woods for the card-board facings of mounts, which veneer facings will admit of being French-polished, and of receiving various kinds of ornamentation. In making album mounts he first backs leaves of veneer with paper or cloth, and then cuts out the openings for the pictures. He next places two leaves back to back, so that the openings in each shall correspond, and applies card-board filling at certain parts, so as to leave space between the leaves of veneer for the insertion of the photographic or other pictures, as is well understood; then, by glue or other cement applied to the filling pieces and leaves where in contact therewith, he connects the leaves of veneer together. *Patent abandoned.*

2883. J. Chattwood. *Improvements in ventilating rooms and cellars.* Dated October 27, 1862.

This invention has for its object the ventilation of rooms and cellars, the equalizing of temperature, and the prevention of inconvenient drafts or currents in rooms containing fires. To accomplish this the patentee makes the bars of the grate or fire-holder hollow or tubular, and perforates the said bars with any convenient number of holes or apertures; or he makes the sides of the grate or fire-holder, or the jambs or sides of the fire-holder, with chambers or cavities, and places any convenient number of perforations or apertures therein for the air to pass through. The air is supplied to the said bars, chambers, or cavities from the cellar or room to be ventilated by means of apertures, channels, or pipes, as may be required. He also admits the air to the said bars, chambers, or cavities, when required, by means of pipes or channels communicating directly with the external air outside the building. He also uses where convenient a hollow cone or cones, or other shaped figure or figures, containing any convenient number of apertures or perforations, and places the same near the fire, and in communication with the external air or the room to be ventilated. A valve or regulator is placed in any convenient part of the said pipes or channels for the purpose of regulating the quantity of air passing through the said channels, pipes, or apertures. The said apertures or perforations are made of any convenient part of the before-named portions of the apparatus, but he prefers to place them in such a way that dust or ashes may have little tendency to choke or stop the free passage of air. *Patent completed.*

2884. J. H. Johnson. *Improvements in rotary engines.* (A communication.) Dated October 27, 1862.

This invention relates to a peculiar construction and arrangement of rotary engine, wherein a continuous rotary motion is obtained by the successive direct action of a number of cylinders and pistons upon two discs placed at an angle with each other; and consists in the employment of a pair of discs, one of which has a number of steam ports cast therein, and each disc is fixed on one end of a separate shaft of its own. In place of the two shafts being in the same axial line with each other, they are placed at an angle, so that the peripheries of the two discs will be nearer together at one side than the other. The steam ports or passages communicate by means of flexible pipes with corresponding single-acting cylinders, connected by ball and socket joints with the inner face of one of the discs, the corresponding pistons and rods being similarly connected to the inner face of the opposite disc. A valve in the centre of the disc is so arranged as to admit the steam into each port successively as the discs revolve, the steam entering that port and cylinder which is situate at the point where the edges of the discs are nearest together. As the steam expands, the cylinder and piston tend to separate by their joint action upon the inclined surfaces of the discs, and tend to rotate the same, bringing the next succeeding port and cylinder under the valve, which then receives steam in its turn, and so on; the exhaust taking place through another passage in the valve at a point where the action of the cylinder and piston is no longer of service. Motion is transmitted from these discs by having spur teeth cast thereon gearing into corresponding pinions on a second motion shaft. The bearings which support the shafts of the two discs wheels are made adjustable on their tables so as to regulate exactly the angles of two shafts. *Patent abandoned.*

2885. J. H. Johnson. *Improvements in heating glass furnaces.* Dated October 27, 1862. (A communication.)

This invention relates to an economical mode of heating glass furnaces of all kinds, and consists of an arrangement for employing for that purpose the waste gases from coke ovens. In carrying out this invention, the gas emitted from the coke ovens is conveyed by suitable passages or flues into a fire-brick depositing chamber, where heavy cinders or heavy matter carried over are deposited, the current of the gas being retarded by having a division wall extending downwards to near the bottom of the chamber, under which partition the gas has to pass before it can escape. A syphon pipe opens into one end of the depositing chamber at the top thereof, and communicates with the upper part of a condenser. This condenser consists of a metal vessel having an expanded tube fitted to the under side of the cam, and reaching down to near the bottom of the vessel, the largest diameter of this tube being at the lower end, whilst its smaller end opens direct into the second mouth of the syphon pipe. A rose jet is contained inside the expanded tube, and is supplied with water from a cistern above, so that as the gas passes from the depositing chamber it is cooled by passing through the stream of cold water, and, the tar being condensed, falls to the bottom of the vessel. From the upper part of this vessel the gas freed from the tar passes through pipes to the glass furnace, previous to which it is heated and mixed with a blast of air, and directed through tuyeres into the chamber of the furnace containing the glass. *Patent completed.*

2886. H. C. R. Joubert, *Improvements in raising music chairs, stools, or seats, which entirely supersedes the original screw now in use.* Dated October 27, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2887. F. Lipscombe. *Improvements in purifying water.* Dated October 27, 1862.

This invention relates to the treatment of vegetable matter preparatory to its conversion into charcoal for filtering purposes. According to this invention, the whole or portions of any tree or shrub is or are cut into small pieces, and steeped in a strong solution of caustic soda, or caustic potash, or a combination of the two, in any proportion, for several days. The aforesaid pieces are then taken out of the solution, dried, and converted into charcoal in well-covered crucibles, or otherwise. The charcoal is afterwards ground and treated in the usual manner. It may then be used by itself, or in combination with one or more plates or slabs of porous stone, or with ordinary charcoal, or in combination with one or more of the materials which are used by filter-makers as filtering media for impure water to pass through. *Patent completed.*

2888. W. J. WILLIAMS. *Improvements in the construction of field-rakes for agricultural purposes.* (A communication.) Dated October 27, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2889. T. PILGRIM. *An improvement in locks, bolts, atches, and other fastenings.* Dated October 27, 1862.

This invention consists in the addition of a supplementary gravitating or spring lever and bolt fixed to, in, or upon an ordinary lock, so as to be actuated simultaneously with the bolt or latch of such lock, and with the same key, such key being formed with an additional limb for actuating the said supplementary bolt or latch. The supplementary bolt or latch can be added to locks, latches, and spring bolts as at present fixed to any door, chest, or other enclosure. Locks thus constructed, or to which this improvement is added, cannot be opened without the proper key, or a duplicate thereof. When the addition is made to existing locks, the limb for actuating the supplementary bolt can be added to the ordinary key. The bolt of an ordinary lock, fitted with this improvement, cannot be actuated without locking or unlocking the supplementary or safety bolt. *Patent completed.*

2890. F. L. H. W. BUNGER. *Improvements in self-acting apparatus for discharging the water resulting from the condensation of steam.* (A communication.) Dated October 27, 1862.

This invention consists in adapting to vessels wherein steam is used the employment of certain self-acting mechanism, whereby the water produced by the condensation of steam is more easily got rid of than has heretofore been the case, at the same time preventing the escape of steam. To effect this, the inventor places within a pipe in connection with the steam vessels a tube or pipe of smaller diameter filled with water, and closed or solid at one end, whilst at the other end it is closed by means of a disc or plate of india rubber or other suitable elastic material fixed in any convenient way, so as to make it perfectly water-tight. He places inside the pipe in connection with the steam vessel a valve seat. The lower end of this pipe is fixed to a cistern. To the inside of this cistern he attaches a bracket or stop. On the tube or pipe of smaller diameter he attaches a valve or lid. The lower end of this tube on which the india-rubber disc is fixed rests on the bracket or stop above mentioned. *Patent completed.*

2891. J. J. RIDGE. *Improvements in treating certain farinaceous substances applicable to infants' or invalids' food, and in appartus to be employed therein.* Dated October 27, 1862.

This invention has reference to an improved process for treating and imparting medicinal properties to wheaten flour, oatmeal, Indian corn, rice, or like farinaceous substances, and obtaining therefrom a purer and more nutritious food, applicable to infants or invalids, than at present, and consists in subjecting the said farinaceous substances to a roasting or drying process, contained within closed cylindrical vessels or chambers surrounded by and maintained under heat uniformly for about six hours at the temperature of boiling water, steam, or otherwise; suitable outlet pipes or passages in the apparatus being provided for the escape of vapour or gases evolved during the process. The ingredients thus prepared are then to be mixed or incorporated with other matters of an alkaline or saccharine nature, in such proportions as may be found necessary for allaying acidity or otherwise rendering the same soothing and agreeable to the palate. *Patent completed.*

2892. P. E. PLACET. *An improved process of engraving.* Dated October 27, 1862.

In carrying out this invention, the inventor spreads on a clean glass a pretty thick coat of Judea bitumen, which, when desiccated, he exposes, under a stereo or other like plate (cliché), or surface carrying the design to be engraved, in a frame, to the action of light. On being removed from the frame, the impressioned surface is covered with a coating of gelatine, and when dry the whole is plunged in a mixture of naphtha and benzine. The liquid penetrating under the coating removes the soluble parts in contact with the glass, and soon the pellicle of gelatine becomes attached, taking with it the parts which remain insoluble. He transports the sheet of gelatine with the design or figure upwards to a flat surface of glass or metal. If the proof be examined it will be found that the non-dissolved bitumen which constitutes the design or figure will appear in relief, which will be higher the more deeply the light has penetrated. The reliefs are similar to those produced upon a print by the lines in an engraved plate. Then to obtain a plate engraved in intaglio, it is accomplished by taking the mould of this surface in relief; and by having recourse to galvano-plaster, or to the electrotype process, metal plates similar to the mould are obtained, which can be used as in copper-plate printing. *Patent completed.*

2893. G. LINDEMANN. *Improvements in the manufacture of bricks, tiles, slabs, and other articles of earthenware, or other plastic material.* Dated October 27, 1862.

This invention relates—1, to a method of bringing the clay or other plastic material into a condition for being moulded. For this purpose the patentee causes it to be forced through slits or other openings formed around the periphery of a cylinder, and through which it is again propelled, so as to be delivered to any convenient receptacle, or at once into moulds. When the articles are formed by being forced through moulds, and then cut off, he causes them to abut against a surface retained by levers, which, when the material has been severed, turns downward and deposits the moulded article on to a travelling apron, or other such apparatus. Another part of the invention relates to the construction of hoppers for delivering plastic materials to rollers or other apparatus which are to operate upon it, and consists in forming the sides of such hoppers of travelling surfaces. *Patent completed.*

2894. A. PEEK. *Improvements in apparatus for evaporating saccharine and saline solutions.* Dated October 27, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2895. T. RICHARDSON. *Improvements in the manufacture of sulphate of soda.* Dated October 27, 1862.

This invention consists in submitting common or rock salt to an elevated temperature, and employing the same when so heated with sulphuric acid for the manufacture of sulphate of soda. *Patent abandoned.*

2896. J. HOWIE. *Improvements in machinery or apparatus for regulating the supply of solid or liquid bodies to mills, or other apparatus used in mixing or preparing plastic matters.* Dated October 27, 1862.

Under one modification of apparatus, as arranged according to this invention, for preparing a plastic mixture of fire-clay and water suitable for the manufacture of fire-clay goods, it consists of a cylinder in which is arranged a screw. This cylinder is, by preference, placed in a vertical position, and the internal screw is made a little less than the diameter of the cylinder, so as to revolve freely therein, but without allowing the solid matters to pass down between its periphery and the inside of the cylinder. The screw is connected by means of suitable gearing with an engine or other prime mover, so as to impart a uniform rotary motion thereto. The upper part or feeding end of the cylinder being placed in connection with a suitable receptacle of the ground fire-clay, it passes down through the cylinder at a uniform rate, impelled by the motion of the screw, and is carried into the pug mill. The supply of water is regulated by means of a valvular apparatus arranged for the purpose. *Patent abandoned.*

2897. J. CHALMERS. *Improvements in armour plating ships of war and fortifications.* Dated October 28, 1862.

This invention has for its object improvements in armour plating ships of war and fortifications, and consists of the following combinations of iron with timber, or other light and compact substance, or of the arrangement of iron alone, in the manner hereinafter described. The backing for the armour plates to rest against consists of a frame of the following description :—A plate (or plates) of iron an inch in thickness, more or less, forms the bottom of the backing frame, and to the said plate (or plates) are attached longitudinally, vertically, or diagonally ribs of iron half an inch in thickness, and nine inches in width, more or less. The said ribs are to have a T or angle edge for attaching them to the plates at right angles, and they are to be six inches apart, more or less. The spaces between the said ribs are to be filled with timber, or some light and compact substance, so that the timber or other substance will be flush with the outer edges of the ribs, and thus form—with the said ribs and bottom plates to which the said ribs shall be attached with rivets or otherwise—a backing frame for the support of the armour plate. In cases where great strength is required, there are to be cross ribs inserted between and at right angles to the ribs aforesaid, thus forming the backing frame into cells, which may either be left empty or filled with timber, having the grain at right angles to the bottom of the backing frame, or otherwise; or the cells may be filled with some other light and compact substance. But in either case the plate or bottom of the backing frame shall be placed towards the ship or fort, and farthest from the armour plate. In the case of ships or forts built of iron, timber planking of four inches in thickness, more or less, or some other elastic or yielding substance, is to be placed between the backing frame aforesaid and the skin of the ship or wall of fort, in order to lessen the rigidity of the combined bodies. In fastening the armour plates to the sides of a ship or iron fort, the backing frame must be first placed against the ship or fort, and be bolted thereto independently of the fastenings of the armour plates. The armour plates are then placed against the backing frame, and fastened through the backing frame to the ship or iron fort by means of bolts and nuts. The head of the bolt has a stepped conical neck with three steps, more or less, which neck fits into a corresponding hole in the armour plate, so that the shoulders or bearers of the several steps of the neck may prevent the bolt from being driven through the plate when struck on the head by a projectile. *Patent abandoned.*

2898. E. HOOPER. *Improvements in roofiing tiles.* Dated October 28, 1862.

The patentee claims—1, The construction and employment of tiles or slabs having sunken channels upon their upper surfaces free from any rebate, shoulder, or raised portion that would prevent the tiles from lying close together on their general surfaces, which channels are more or less covered by the tile or tiles above them, and having further grooves formed on their under surfaces, which grooves fit exactly over the before-mentioned channels in the tiles beneath, thus forming drips over the same. 2, The construction and employment of tiles having channels and grooves, as ascribed in the first claim, in combination with such a form of the tiles that the meeting corners of two contiguous tiles are cut off, so as to form meeting edges in which notches are made for intercepting the passage of the water, substantially as described. 3, The construction and employment of tiles or slabs, made or cut out of any suitable material, in which those corners that come in contact with other tiles or slabs lying in the same plane are cut off to such an extent as to afford the requisite amount of lap, so as to maintain the external edges of the tiles upon the roof in continuous lines, the particular shape, general formation, and arrangement of the tiles affording at the same time the most efficient covering and protection from the rain, with the least amount of lap, and without the necessity for stopping of any kind, thus ensuring the greatest possible economy in weight and material. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated Jan. 8, 1863.

66. R. Groggan, 27, Hereford-road North, Bayswater, W. New and improved propellers for vessels driven by steam or other power.

Dated Feb. 11, 1863.

369. H. Donald, Johnstone, Renfrew, North Britain, engineer. Improvements in machinery for shearing, punching, and riveting metals.

Dated Feb. 18, 1863.

445. J. Platt, mechanical engineer, and W. Richardson, Oldham, Lancaster. Improvements in machinery or apparatus for cleaning cotton from seeds.

Dated March 17, 1863.

715. J. Cox, Georgie Mills, Edinburgh, glue maker. Improvements in swimming baths, and in apparatus for swimming, part of which apparatus is applicable to sailing or moving vessels in a circle.

Dated April 6, 1863.

871. E. T. Hughes, 123, Chancery-lane, patent agent. Improvements in machinery or apparatus for manufacturing the ornamental tips of parasols, umbrellas, and similar articles. (A communication.)

Dated April 16, 1863.

960. A. Samuelson, 28, Cornhill, engineer and iron ship builder. Improvements in the construction and arrangement of machinery and apparatus for the manufacture of oil.

Dated April 17, 1863.

966. J. Goucher, Worksop, Nottingham, ironfounder, engineer, and machinist. Improvements in steam boilers, and in regulating the admission of air into the furnaces of steam boilers.

Dated April 20, 1863.

978. P. G. Rowell, 17, Castle-square, Brighton, Sussex, and H. Holt, 14, Red Cross-street, Brighton, Sussex. A better and more economical mode of securing the bands of locomotive engine and tender springs, also a new method of applying the same.

Dated April 23, 1863.

1012. T. Richardson, Newcastle-upon-Tyne, chemist, and J. C. Stevenson, Jarrow Chemical Works, Durham, chemical manufacturer. Improvements in the manufacture of sulphate of soda.

Dated April 24, 1863.

1016. W. N. Wilson, 144, High Holborn, and J. G. Grey, 97, Cheapside. Improvements in machinery for sewing and stitching.

Dated April 25, 1863.

1034. J. Dunbar, jun., and J. W. Woodford, 12, Sutherland-street, Walworth. Improvements in apparatus for steering ahd manœuvring ships and vessels.

1040. A. Legras, 64, Davies-street, Berkeley-square, confectioner. Improvements in machinery or apparatus for making ices.

Dated April 28, 1863.

1064. W. Clark, 53, Chancery-lane, engineer and patent agent. Improvements in machinery for the manufacture of paper, and of the various kinds of boards produced from fibrous substances. (A communication.)

1066. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in drying and cooling grain, and in the machinery or apparatus employed therein. (A communication.)

Dated April 29, 1863.

1082. M. Barland, Mount-street, Grosvenor-square, and E. H. C. Monckton, Cavendish Club, Regent-street. Improvements in apparatus for withdrawing milk from cows and other mammiferæ, and for conducting it when withdrawn to appropriate receivers. (A communication.)

Dated April 30, 1863.

1090. E. Mitchell, Cams Alders Lodge, Fareham, Hampshire. Improvements in reaping and mowing machines.

1098. W. G. Craig, Cannon-street, engineer. Improvements in feed apparatus for steam boilers. (A communication.)

Dated May 2, 1853.

1100. T. L. Bissell, Charleston, South Carolina, North America. An improved apparatus for charging breech-loading cartridges.

1102. J. W. Gibson, 31, Lower Ormond Quay, Dublin, and W. Turner, Hammersmith Iron Works, Dublin. Improvements in springs to be used for railway buffers, draw-hooks, and also for carrying springs of railway carriages and other vehicles.

1104. J. Purdey, Oxford-street, gun manufacturer. Improvements in breech-loading firearms.

1106. J. B. Dubreuil, 108, Rue du Faubourg St. Denis, gentleman. Improvements in carts, waggons, and other vehicles.

Dated May 4, 1863.

1112. B. G. Sloper, Walthamstow, Essex, engineer. Improvements in apparatus for separating metals from earthy and other matters mixed with them.

1114. F. Applegate, Bradford-on-Avon, Wilts, woollen manufacturer. Improvements in spring balances and pressure gauges.

Dated May 5, 1863.

1118. E. Cheshire, Birmingham, surgeon. Improvements in apparatus for intercepting the solid portions of the soil of water closets.

1120. R. A. Brooman, 166, Fleet-street, patent agent. A new fabric suitable for trimmings. (A communication.)

1122. P. Bradshaw, Earls Barton Mills, Northampton. Improvements in mounting or hanging mill stones for grinding grain and other substances.

1124. W. Glover, South Shields, Durham, ship chandler. Improvements in means or apparatus to facilitate the steering of ships and other vessels.

1126. R. B. Cochran, 48, Flemming-road, Kennington-road, machinist. Improvements in sewing machines, and in apparatus connected therewith.

Dated May 6, 1863.

1123. J. T. Ward, Swansea, Glamorgan, carriage builder. Improvements in carriages.

1130. S. Hibbert, shopkeeper, J. Lawton, smith, and J. Kay, Manchester. Certain improvements in apparatus for cleansing potatoes, and in decorticating the same and other esculent roots.

1134. T. Beesley, Symond's-inn, wine and beer merchant. Improvements in the construction of cases or boxes for carrying and packing bottles.

1136. C. W. Atkinson, 34, Montague-place, Russell-square. An improved steam or other motive power engine.

Dated May 7, 1863.

1138. J. Park, Bury, Lancaster, engineer. Improvements in communicating motion to machinery for manufacturing paper pulp.

1140. P. Bourne, Whitehaven, Cumberland, colliery viewer. Improvements in miners' lamps.

1142. A. Stanley, Walsall, Stafford, covered buckle manufacturer. Certain improvements in the mode of finishing clasps and other such like metallic connectors, and which said mode of finish is also applicable to other purposes.

1144. T. Small, Bargate, Boston, Lincolnshire. Improvements in motive power machinery.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated May 9, 1863.

1163. W. E. Gedge, 11, Wellington-street, Strand. Improvements in the manufacture of paper, stuff, or pulp from certain vegetable substances. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, May 19, 1863.

31. E. B. Keeling. Lighting halls, theatres, and other buildings.

42. C. T. Judkins. New alloys. (A communication.)

43. J. Eckersley. Looms for weaving.

46. J. A. Knight. Printing presses. (A communication.)

48. E. V. Gardner. Treatment of petroleum and mineral oils.

49. J. G. Dahlke. Machinery for cutting clay in the manufacture of bricks, tiles, and similar articles. (A communication.)

54. T. F. Cashin. Covering wire, crinoline steel, or hoops for skirts.

70. R. T. and R. Monteith. Manufacture of dyes from aniline. (A communication.)

75. C. E. Gray. Wringing machines.

86. W. Grove. Apparatus for sawing wood.

87. R. Lüthy. Hydrostatic presses.

88. M. Vogl. Fastening for bags.

94. E. Stevens. Ovens, hot plates, and cooking apparatus.

98. A. I. Mahon. Screw and paddle propellers, and a submarine propeller, also applicable to the raising and forcing of water.

101. J. B. Fenby. Apparatus to be attached to pianofortes, organs, and other similar keyed instruments, for printing the score of any music performed on the said instruments.

103. D. and J. Tannahill. Rivet-making machinery.

108. W. Southwood. Machinery for manufacturing nails or brads.

111. L. Lescuyer. India-rubber over-shoes or goloshes.

120. G. A. Biddell. Machines for pulping turnips and other vegetable substances.

122. J. Lawson. Apparatus for holding castings and other pieces whilst being planed and shaped.

125. T. Wilkinson. Manufacture of tubular steam boilers.

139. J. W. Child. Apparatus employed in spinning and weaving.

143. R. A. Brooman. Machinery for the manufacture of lace and other fabrics. (A communication.)

145. L. Verdure. Slubs or rovings.

152. I. Ashe. Apparatus for preventing sea-sickness.

153. J. Combe. Machinery for spreading, drawing, and carding flax.

167. J. Mosheimer. Machinery for crushing and grinding quartz.

183. J. Holt. Willowing and opening cotton.

202. N. Wood and J. Stockley. Apparatus for grinding, smoothing, and polishing plate glass.

213. C. Turner. Manufacture of felted fabrics.

227. J. B. Fell. Working railway engines and carriages on steep inclines.

246. W. E. Gedge. Apparatus for fastening by screws boots, shoes, and other articles composed of leather. (A communication.)

254. W. Conisbee. Cylindrical chromo-lithographic printing machines.

325. W. Betts. Apparatus for applying metallic capsules to bottles.

331. B. F. Bates. Cannon, and in projectiles to be used therewith. (Partly a communication.)

370. E. T. Hughes. Apparatus for drilling wood, stone, iron, or other materials. (A communication.)

522. E. B. Wilson. Manufacture of an alloy or alloys of titanium and iron.

540. A. Capello. Apparatus for glazing Morocco leather.

696. J. C. Richardson. Construction of ships.

756. G. A. Biddell. Locomotives, usually called traction engines, to be used on common roads.

875. J. Macintyre. Manufacture of knobs and other articles in china and earthenware.

893. D. J. Cooke. Compositions for sizing, stiffening, and colouring yarns and textile fabrics.

895. F. J. Risse. Haft or handle for holding tools or instruments of various sizes.

956. I. Baggs and W. Simpson. Purifying and treating coal gas, sulphuretted hydrogen, and other gases containing sulphuretted hydrogen, and in obtaining sulphur, sulphuric, and other acids in such treatment.

994. W. E. Newton. Wrenches. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed May 15, 1863.

3087. W. Dobson.
3093. J. Orbös.
3094. P. H. Klein.
3095. W. H. Burnett.
3096. W. P. Houghton.
3097. C. W. Harrison.
3098. C. Neild and J Hopkinson.
3103. L. Lenzberg.
3105. J. Chalmers.
3108. J. Orbös.
3109. R. A. Brooman.
3116. C. Stevens.
3118. F. Fletcher.
3120. J. W. Child.
3121. F. Seiler.
3126. C. Hadfield and W. A. Atkins.
3132. T. Walker.
3138. S. and C. Deacon.
3251. R. D. Kay.
399. J. C. Jeffcott.

Sealed May 19, 1863.

3127. J. Townsend.
3133. C. Wagner.
3137. C. A. Orth.
3139. A. Sutton.
3140. W. E. Gedge.
3141. W. E. Nethersole and C. Buckland.
3144. C. Powell.
3155. W. Tatham.
3159. A. L. Woolf.
3184. W. Clark.
3189. J. H. Johnson.
3193. W. Clark.
3207. Rev. H. Moule.
3221. P. W. Reuter.
3223. B. Oldfield.
3270. H. A. Bonneville.
3310. S. B. Whitfield.
3326. T. E. Vickers.
3383. E. Lepainteur.
3393. A. V. Newton.
24. E. Skull and E. Mealing.
253. J. Platt.
262. H. A. Bonneville.
458. N. Thompson.
517. F. A. Gatty.
521. W. Readman.
638. G. T. Bousfield.
716. W. E. Newton.
734. G. Haseltine.
770. G. Davies.
798. W. Blake.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

1193. G. H. Barth.
1195. J. Higgins and T. S. Whitworth.
1220. J. Cole.
1225. J. D. Dunnicliff and S. Bates.
1226. W. Greeves.
1235. J. Lees.
1266. W. Clissold.
1270. T. Cope.
1300. G. De Laire and C. Girard.
1382. G. Hadfield.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

1178. G. Carter.
1185. J., T., and G. Wilkes.
1219. J. C. Pearce.
1267. W. E. Newton.
1513. A. Shanks.

LONDON, FRIDAY, MAY 29, 1863.

HIGH PRESSURE BOILERS.

COULD the shade of the illustrious Watt make a little tour through our manufacturing districts, the timid ghost would need but a glance at the pressure gauges on the boilers now in use, to find a sufficient inducement to return to the regions from whence it came. Forty years have done much to extend the use of far higher pressure than Watt ever contemplated. Many idle prejudices—many erroneous notions have died a natural death during the last half-century. The employers of steam power, the class really far more interested than engineers, in improvements, day by day become more alive to the fact, that without expansion there can be little economy; and the use of a pressure which the past generation of engineers would have considered dangerous in the extreme, follows as a matter of necessity.

All civilized nations are more or less employers of steam power; and it is strange enough, that in no country save our own, has any extended prejudice been entertained against high pressures. Belgium, France, and America early perceived the advantages to be derived from their use; the latter country, in particular, has received an unenviable notoriety for the reckless disregard of human life displayed in the working, far more than the construction, of some of her river steam-boats; but, that these accidents are not due to the use of high pressure steam alone, is proved by the fact that the greatest number of accidents, taking the United States as a whole, have been occasioned by boilers working steam of a pressure under 50 lb. to the square inch.

England and America have each been the exponent of a separate system, each capable of giving good results, while the best only can be expected from their union. Each country has followed the teaching of its own great apostle of steam power. England received the steam-engine low pressure from James Watt, and low pressure for many years she has kept it; America got the steam-engine high pressure from Oliver Evans, and high pressure her people have retained it; by grafting Watt's condenser, and the principle of expansion, on Evans' high pressure, we can alone secure such results as 1,980,000 lb. raised a foot high in an hour, by the consumption of little over one pound of coal—a result so astonishing, that nothing but accurate and well-attested experiments, could convince us that practice might be made to wait so closely on theory.

Although high pressure steam is just as safe as low pressure, when raised in properly constructed boilers, yet in order to secure all the elements of safety, it is found necessary to resort to forms and principles of construction very different from those suitable to low pressure generators. In consequence, their variety is almost endless; good, bad, and indifferent, we could count some hundreds of schemes in the Patent Office for the construction of boilers to raise steam from 100 lb. to 500 lb. per square inch. The fact is that many practical difficulties are involved, which have proved strong stimuli to the combative faculties which induce inventors to go in search of such obstacles, merely for the pleasure of overcoming them. Our present purpose is to glance at some of the most important desiderata in the construction of high-pressure generators, some of the more obvious difficulties to be encountered, and a few of the plans hitherto adopted with most success.

Boiler explosions have occurred ever since the day water was first boiled in a closed vessel; and boilers will explode, for anything we can see to the contrary, to the end of time. We feel no hesitation in endorsing the words of Dr. Alban, and repeating, that our great guiding principle should be "so to construct the boiler that its explosion may not be dangerous," a result easily attained by generating the steam within small tubes, or flat spaces strongly stayed, so that the boiler really consists of an assemblage of small generators, more or less detached and distinct one from the other. By this means, not only is great strength secured, but the quantity of steam and water to be suddenly dispersed is so much reduced that little danger can result from an explosion. The small tubes are invariably the weakest parts of such boilers, and being thin, they open quietly, without flying in pieces; hence none of the destructive results due to the propulsion of heavy masses of metal to great distances can ensue. Boilers of this construction are usually termed "tubulous," to distinguish them from "tubular boilers," in which, instead of the small tubes containing steam and water, they are made use of as flues to convey the products of combustion to the chimney.

Very excessive pressures have been raised years ago in these tubulous boilers—pressures, indeed, before which anything we now see in daily use, sinks into insignificance. Jacob Perkins has employed a pressure of 500 lb. on the square inch for propelling bullets; Dr. Alban, of Plau, in Mecklenburgh, worked an engine in London, many years ago, at a pressure of 1,000 lb. on the square inch with the greatest success. Perhaps the nearest approach we have had to these pressures of late years, was in an engine exhibited at the Agricultural Show at Salisbury in 1857, by Mr. Collinson Hall. This engine was worked at a pressure of 300 lb. to the square inch, and gave an indicated horse-power for each 1·25 lb. of coal consumed per hour. The boiler was, we believe, of the upright tubular class, some 2 ft. 6 in. in diameter, and 6 or 7 ft. high, with a circular fire-box in the lower part, and 40 or 50 vertical flue tubes passing through the water and steam (which last they superheated considerably) to the uptake. The explosion of such a boiler as this, would of course be attended with disastrous results if the outside shell gave way. And although such boilers are very compact, and capable of standing very high pressures with safety, 'yet they are in general so subject to priming, and difficult to clean, deposit settling in a hard mass on the crown of the fire-box, from which it cannot be removed, that their use is seldom or never to be recommended. Mr. Hall is not, of course, the inventor; it would be difficult indeed to say who is.

Mr. Martin Benson invented and patented a very good form of high-pressure boiler three or four years ago. As it was brought a good deal before the notice of the public at the time, our readers may perhaps be sufficiently acquainted with it to prevent the necessity of a detailed description, for which we have not space. It consists of a great number of small tubes traversing a vertical fire space; the ends of all the tubes are so connected by a very simple and ingenious arrangement, quite protected from the action of the fire by the side walls, as we may call them, of the fire space, that they become one. A vertical receiver of considerable height and moderate diameter is placed at the side of the generator. A small pump, fixed at the bottom of this, and worked by the engine, forces the water in a continuous current through the tube. Entering at the bottom and passing backwards and forwards through all its windings, it is discharged at the top, mingled with steam, into the upper part of the receiver, or steam chest, where the water, separating from the steam, falls to the bottom, while the steam flows through a suitable pipe to the engine. This boiler is said to have given very good results, but has not hitherto met with much favour, owing to a prejudice against the use of the circulating pump. Whether an injector would better answer the purpose of maintaining a current remains to be proved.

Mr. Benson's boiler may perhaps be regarded as the best of a class of generators, in which the distinguishing principle is the forcing of water through a continuous coil of tube of small diameter, exposed in whole, or in part, to the action of a furnace. From various causes these boilers have never met with extended adoption.

Dr. Alban's may be regarded as the type of a far superior class of generator, in which a large flat vessel, with the sides very heavily stayed together, usually called the "heart," is made the means of communication between a very large number of tubes, about 4 in. in diameter, and 6 or 8 ft. long; one end of each of these tubes is firmly fixed in the front plate of the heart, which stands just over the fire door. The tubes traverse horizontally a fire space some 6 or 8 ft. high, built of brick on three sides, the heart forming the fourth. All the tubes are set on a slight incline from the heart downwards, so that the steam may, by its own levity, rise towards and enter the heart, while the water, by its gravity, flows into the tubes to replace that evaporated. The ends of the tubes furthest away from the heart are stopped by moveable covers, which can be removed to clean the tubes, as at this end they pass through the brick wall of the fire space, in order that they may expand freely. A simple arrangement of plates in the heart conveys the steam, as soon as it leaves the tubes, to one side, where rising, it passes through a suitable tube into a separator about 12 in. in diameter, and some feet long, placed horizontally on top of the generator, but not exposed to the action of the fire; the water which rises with the steam flows back from this separator through a second pipe, which descends at the other side of the heart, and rising from it re-enters the tubes, and is in part converted into steam as before. This boiler, though very expensive, is an extremely durable and economical generator of steam, from 100 lb. to 300 lb. on the square inch; and the tubes being the weakest part of it, an explosion never leads to any dangerous results, from the reasons already pointed out. It enjoys a very good reputation on the Continent, although we believe never yet used in Great Britain.

A class of boilers much the same in principle but very different in construction, has been gradually creeping into favour of late years. The distinguishing characteristics of this generator are an outside shell, square, oblong, or circular, in horizontal section, according to circumstances, which has a second shell, or fire-box, about 6 in. smaller, placed within it, much as the inside fire-box is fitted in a locomotive. In the bottom of the inside box, which is heavily stayed to the outside shell, is placed the fire-grate, while the upper part is traversed by a number of small tubes feruled into the inside shell at each end; the flame and heated air pass upwards between these tubes to the chimney, which is usually placed directly above.

This kind of boiler, although cheap, possesses many disadvantages; it is very heavy; it is impossible to clean the tubes without taking out the whole inside box; it is very difficult to keep the tubes tight at the ends; and as it is frequently constructed without any regard to correct principles, it has in addition been accused of excessive priming, which is likely enough when we consider that the tubes are not only very small, but put in on a dead level, so that a constant contention goes on between the water and the steam—one struggling to get out, the other to get in. The tubes should always be put in on an incline of at least 1 in. to the foot, when the steam will escape quietly from the highest end, while the water will enter quietly at the lowest; a constant circulation is thus kept up, which not only permits the supply of dry steam to the engine, but conduces materially to the durability of the boiler.

Whether a boiler can be produced which will permit the use of sea water under high pressures, is a question we need scarcely enter on; the success which has attended the introduction of surface condensation rendering such a boiler needless. Still, certain mechanical difficulties stand in the way of the general adoption of tubulous boilers on board ship; one of the most important is the difficulty of obtaining room enough for the introduction of a new tube in case of accident. This difficulty is not experienced when introducing an ordinary flue tube, because such tubes invariably present their ends to the firing space, which is usually 8 ft. or 10 ft. wide; but, owing to difficulties entailed by the position of the uptake, the tubes, when horizontal, must almost unavoidably run parallel with the firing space when the stoke-hole bulk-heads preclude the withdrawal or replacement of the tubes; another, and still more serious objection, is the great height of boiler necessary when tubes 4 in. in diameter are employed. Unfortunately, when of smaller size, they are never durable, being very liable to boil dry for a few seconds, when of course they become overheated, and again cooled down by the rush of the re-entrant water; they are thus soon burned out; large tubes always "steam quietly," and are found durable enough. In consequence of these difficulties, many boilers have been introduced from time to time, in which the steam and water are contained in a large number of flat-sided vertical spaces, well stayed, and arranged like books on a shelf, spaces being provided between them for the circulation of the flame and heated air. Such boilers are all more or less complicated, heavy, and expensive; and although the principle is good, it still requires much improvement before it can be considered worthy of general adoption. Marine boilers with vertical water tubes, have met with much favour in America, and seem to deserve the good character they bear. Although horizontal surfaces are invariably the most economical, yet the practical exigencies of marine boiler construction, often dictate a recourse to vertical surfaces as most convenient.

A rather singular arrangement of tubes is sometimes adopted in American steam fire-engines. A large number of moderately-sized tubes descend from a strongly-stayed water and steam space right down to the grate, which they surround; the lower end of these tubes is stopped. Within each of them a second tube of much smaller diameter descends nearly to the bottom. The water continually descends though this tube, and ascends mingled with steam in the space between the two; a constant current being thus effectually maintained. The products of combustion escape through flue tubes fitted in the water space above.

It is a mistake to imagine that a small quantity of water is absolutely necessary to the rapid generation of steam. We have seen steam raised in a small road locomotive, with an ordinary tubular boiler, from 80 lb. to 100 lb. in one minute and a half, or at the rate of 13 lb. in a minute.

Before concluding this article, we would impress on our readers that nothing is more dangerous than the raising of steam to excessive pressures in boilers of a couple of feet in diameter. The explosion of such boilers, especially if the metal is thick, is certain to be attended with the worst results; and from their small size, it is almost impossible that their workmanship can be as good as when a larger diameter is adopted—say 3 or 4 ft. Boilers of these sizes can be, and are daily, worked with safety under pressures of 150 lb. to the inch; and, all things considered, if no increase on that pressure is desired, we know of nothing safer or more economical as a generator than a well-made, properly-proportioned locomotive boiler.

NOTES OF THE BIRMINGHAM MANUFACTORIES.

UNDER the above head we intend presenting our readers with short notices of some of the most celebrated branches of trade which have rendered Birmingham famous. As our limited space prevents our entering into minute details, we purpose, without neglecting anything which is necessary to enable our readers to thoroughly understand the subject on which we write, to point out only a few of the more remarkable features of trade and manufacturing operations, which are either singular in themselves, not generally known, or tend powerfully to cheapen the products of industry. The subject we have chosen for this week is the manufacture of electro-plated goods, as carried on at Messrs. Elkington's establishment.

In the arts or sciences we have few instances of the successful development of new inventions or discoveries in short spaces of time; not only is the growth of ideas gradual, but experiments undertaken by private individuals, to confirm or test the actual value of new inventions, frequently extend not only over months but even years, and then require further development at the hands of the manufacturer. In chemical science especially, we find that the most refined laboratory investigations seldom prove of more value to the manufacturer, than just to demonstrate the practicability of any improvement in his art; so many alterations are necessary to suit laboratory practice to all the exigencies of trade on a large scale before a thing can be made to pay, that much time must almost invariably elapse before we see new processes brought successfully under public notice. We meet with a few exceptions to this rule, but none more remarkable than that afforded by the history of electro-plating, which has risen to an importance which places it amongst the most considerable of the Birmingham trades in the short space of twenty years.

Many of our readers may, perhaps, remember that Mr. Jordan, in May, 1839, made his experiments in electro-metallurgy, known to the public through the medium of this MAGAZINE. Professor Jacobi's investigations, too, were made public in England about the same time; but it was not for some years afterwards that the subject was taken up by Messrs. Elkington and Mason, and carried by them, under many difficulties, to its present perfection.

Messrs. Elkington carry on business in a large quadrangular pile of buildings in the northern quarter of the town; and it may not prove uninteresting to mention that such is the value of space, that a considerable portion of the factory is built on arches over the old Birmingham canal.

The first points worthy of notice are the magnificent show-rooms, beautiful in themselves, even without the countless treasures of art displayed within them. Were we writing for the *Art Journal* we might stop to dwell on the beauties which attract the eye at every turn; but as our mission is the practical rather than the æsthetical, we must hasten on with a passing mention of two or three objects of interest—one being a beautiful service in the Pompeian style, remarkable not alone for its beauty of design or workmanship, but for its very peculiar red enamel, only found hitherto on old services, and the art of making which, long lost, has only recently been recovered by Messrs. Elkington. Any enameller can produce a glossy red of any shade, but this is dull or without glaze of any kind, and in consequence produces a very singular effect. The Chinese believe that they alone possess the art. As it is scarcely a suitable subject for a patent, we may observe that the means of producing it remain a secret. In this room also we saw some beautiful photographs and drawings of the silver table presented to the Princess of Wales by the inhabitants of Birmingham. This table was commenced four years ago, not to order, but merely as a work of high art, originating in the enterprise of the firm, its actual cost being no less than £2,000. We also noticed a magnificent centre-piece in silver gilt, presented to Charles Cammell, Esq., of Sheffield, steel manufacturer, by his workmen.

Passing from these rooms we enter another, containing many beautiful groups, formed by the "galvano-plastique" process—one so singular as to merit a good deal of attention. In executing any work, large or small, on this principle, the first thing is to make a suitable design in clay or wax, from which a model is cast in plaster of Paris, and from this again one in a fine composite metal; this last is carefully chased over by artists, who render the casting a complete work of art. On its completion, it is sent to another part of the building, where, after suitable preparation, it has an exceedingly thin coating of copper deposited on, but, owing to the precautions taken, not adhering to it; this thin film of copper, which is an exact copy, to the minutest detail, of the metal model, is then backed up with wax, and being placed in the depositing baths, receives a coating of fine copper, as before, perfectly detached from the mould. This coating may be of any thickness, according to the time the article remains in the bath. It will be understood that very large articles, such as groups, figures, &c., are modelled piece by piece, but the different parts of the model are all put together to receive the final deposit which, when the mould is cut off it, as we cut the skin from an orange, comes out the perfect statue or group, without requiring tooling or operation of any kind, save a simple washing to bring out the fine colour of the copper. It may be worth while to remark that as no shrinkage of any kind takes place, the design, as given originally in the brass model, is found in all its exactness, without the slightest distortion in the finished work. Artists will not be slow to appreciate such an advantage.

On leaving the show-rooms, we enter the studio, where the designs and plaster casts are prepared, and, crossing the canal by a foot-bridge, enter the yard where the large copper depositing houses are situated. At the time of our visit the colossal figures for the Memorial of the Exhibition of 1851, in course of erection in the Royal Horticultural Society's gardens, were being made, the figure of Africa having just been removed from the bath. As our readers are doubtless aware, the design includes very beautiful figures of Europe, Asia, Africa, and America, at the corners, surmounted by a figure, in the original design of Her Majesty, but since altered to that of the late Prince Consort. Two or three of the figures have already been sent to their destination. The extreme accuracy with which the minutest detail of the original design is given in the finished statue, is sufficiently remarkable. As may be supposed, the depositing vats are of great size, one of the six or seven in the room being no less than 15 ft. long, by 10 ft. deep, by 8 ft. wide.

Leaving the subject of statuary, we enter on the general production of electro-plated goods. Our readers are too well aware, doubtless, of the nature of both the old and new processes of plating to require a detailed description of the principles involved, but we think one or two facts are not generally known. Thus, such a thing as "solid silver edges," as they are called, do not exist, in the accurate sense of the term—the edges so called consisting of a very thin plate of silver struck between dies into the form required, two such plates being soldered together with soft solder, the space between them is filled up with some soft white fusible metal, and the whole fastened in its place with soft solder on the dish or other article. We may remark that this course is never employed at Messrs. Elkington's—no necessity, indeed, existing for it, as all the articles are plated on a peculiar composition of copper and nickel, which itself possesses the lustre of silver and its peculiar metallic ring to such an extent that it is rather difficult to determine which is silver and which the baser metal. This compound metal is cast into figures, and rolled into plates and rods by operations so similar to those employed in the manufacture of copper as to need no further comment—dishes, coffee-pots, &c., being all formed from sheets of different thicknesses, and brought into form by the use of the hammer, and sometimes dies put into action by powerful stamping presses. We find one of these in a lower room, which will take dies 30 in. in diameter; some idea may be formed of its size when we state that the solid cast-iron anvil block weighs 13 tons. All the dies are made on the premises, the present stock having cost no less than £75,000, a sum which those acquainted with the tedious and expensive process of die-sinking will not think extravagant. Very many articles are, however, formed solely by the use of the hammer.

There are few processes in the arts more singular than the formation of a tea-pot almost globular in form from a single flat sheet of metal; when we reflect that it is brought to form altogether by the use of the hammer, and that the metal is not only hard, but exceedingly brittle, our wonder does not diminish. A continuous course of annealing goes on from first to last, the workman determining with unfailing accuracy how far he can go without reheating the article. The annealing is performed in a very ingenious furnace constructed on the reverberatory principle; in the bed of the furnace is fixed a circular disc of fire clay, say 4 ft. in diameter, on which the articles to be annealed are placed, when the disc, which is fixed horizontally on a vertical shaft, is caused to revolve slowly, thus exposing them to an equal degree of heat. When they have been maintained at a bright red for a short time they are removed, and suffered to cool slowly, and then returned to the proper shops, where they advance another step towards that ultimate beauty of shape which renders modern plate so celebrated.

Should the tea-pot, vase, &c., belong to the more expensive class, the next operation is to ornament its hitherto plain surface with groups, flowers, &c., in "repoussé" work, in which the devices are raised up on the front of the dish, &c., by hammering corresponding depressions in the back, as in the silver table we have before alluded to; but the process, simple as it may seem, is, nevertheless, one of the most singular in the whole range of the arts. Most persons imagine that it is produced by a small punch, struck by a hammer. When we state that claret-jugs, coffee-pots, &c., are never repousséd until they are otherwise completed as to form, save the spouts and handles, it will be seen that it would be utterly impossible to introduce a chisel and hammer, unless, indeed, the artificer were sufficiently small to creep inside and use diminutive tools there; and really, when we consider the fairy-like character of many of the designs, and the minute accuracy they display, it is no great stretch of imagination to conceive them the work of one of Queen Mab's own artificers; but, as imagination will never repoussé a tea-pot, let us describe the actual process.

The article having been carefully cleaned, smoothed, and brought to a certain degree of polish, first has the design carefully pencilled on its surface. A row of powerful vices stand at one side of the repoussé shop; in the jaws of each vice is fixed a bar of steel about ⅜ths of an inch square; this bar is so bent as to stand horizontally, at right-angles to the vice bench; it is some 15 or 18 in. long, and the end having been drawn to a blunt circular point, is turned up at right-angles to the bar, so as to stand about half-an-inch above it. The point is made very hard and polished; its diameter varies for different work, an average would be about a quarter of an inch. The steel bar is wrapped with soft string from near the point to about 6 in. from the vice. The whole thing is as rough as can be conceived.

The artist, for so we must call him, taking the vase, &c., to be repousséd in his left hand, passes the rod of steel through the mouth, and resting it solely upon the turned-up point, strikes, not the vase, but the steel rod, with a moderately heavy hammer—strikes it downwards be it understood, and of course away from the article. The spring or jar of the rod recoiling by its own elasticity from the force of the blow, in combination with the inertia of the vase, which is held loosely, produces an indentation more or less deep on the inside, accompanied by a proportionate elevation on the outside. A repetition of the process, with a suitable movement of the vase by the skilful hand of the workman, produces all the beautiful details of the most elaborate design. The growth of the pattern under the hands of the artist seems more like a work of legerdemain than a simple result of skill—it is beautiful to see, difficult to describe. We can but hope that our readers understand us.

It is not a little strange that the origin of this kind of work is unknown. The Indian of the Himalaya Mountains, the Persian fire-worshipper, the rudest Italian artificer, use precisely the same means from time immemorial to produce the same result; from one end of the earth to the other, the art is understood and carried on, century after century, without alteration or improvement, save in the design produced—indeed, all attempts at improvement have proved utter failures; no machine can give the peculiar touch of the artist; we might as well endeavour to paint a Rubens or a Titian by machinery. There is, indeed, a false kind of repoussé work produced by striking plates of metal between dies; but, although beautiful enough, it bears little resemblance to the true work.

It must not be imagined, however, that the work is complete when it leaves the hand of the repousseer. From him it passes to other artists, who, filling the vase, &c., with pitch to impart a certain solidity, give it certain small finishing touches by the use of the hammer and minute punches and chisels, by which small depressions are beaten in the outside as they had just before been beaten within; nothing then remains but to attach the spouts, handles, &c., and prepare it for plating by a thorough cleansing.

Few articles of plate being all in one piece, the operation of fastening them together next claims our attention; but we may premise that figures, trees, and filagree work, on a small scale, are all cast from German silver by ordinary processes, and being chased up, are afterwards fixed in their places by hard solder. The foundry arrangements at Messrs. Elkington's are on a very extensive scale, as the production of cast figures, &c., is very great.

We have already said that no soft solder is used for any purpose at Messrs. Elkington's; and owing to the great heat, nearly 1,500 deg. Fahr., required to fuse the hard solder employed, some very peculiar arrangements are adopted. The soldering shop is, as one consequence, about the noisiest shop in the establishment. Opposite each man is a kind of circular tray, capable of revolving on an upright shaft at the will of the workman; these trays are filled with hard charcoal in small pieces, on which the article to be soldered is placed. Along the wall run two pipes or mains—the smaller of those conveys gas, the larger air under a high pressure. Flexible tubes proceed from each and unite into one a few inches behind a nozzle, which has a circular orifice nearly half an inch in diameter; cocks are fitted to each pipe. The effect of this arrangement is that the flame of the gas violently impelled by the current of air with which it mixes just before it reaches the mouth-pieces, issues in a long bluish jet, giving little light but an intense heat—indeed, articles of a considerable size are raised to a bright red heat in a very short space of time after the jet is turned down on them. Our readers will understand that each workman has one of these blow-pipes at his command. The intense heat is due to the intimate mixture of the oxygen of the air with the hydrogen of the coal gas, the general principle involved being, in fact, precisely that of the oxyhydrogen blow-pipe. Some peculiar arrangements are necessary, as may be supposed, to prevent the high pressure air forcing its way into the gas main; by simple means, however, the jet of air rather tends to draw the gas from the main, much on the principle of the Giffard injector. The noise produced by so many blasts, is, however, very considerable when a number of men are at work at the same time. The mere operation of soldering is too well known to present any feature of interest.

On the same floor we find a very elegant application of steam power as a substitute for hand labour. The old process of "planishing," or hammering a plate all over to condense its particles, was both tedious and laborious; here, however, we find a beautiful little machine on the principle of the atmospheric tilt hammer. A bar of steel, about 3½ in. in diameter, turned truly circular, has its lower end finished to a slightly spherical form, while the upper end passes, through a stuffing-box, into a small cylinder, as the plunger does into a force-pump. About the centre of the box, which may be 3 ft. long, a slot is made, within which a cam, fixed on a horizontal shaft, works, causing the bar to make about 150 very short vertical strokes per minute; the speed admits of easy regulation. A suitable anvil is placed underneath, at which the workman sits conveniently, and moving the article to be planished under the hammer, has his work performed for him in a wondrously short space of time, and with an accuracy unattainable by hand. This is almost the only process in electro-plate work where machinery has superseded hand labour, all attempts at its introduction in other operations having proved failures; even the stamping presses, of which there are seven or eight, being all worked by hand, except the large one we have already referred to, and one other of smaller dimensions.

We next enter the depositing shop, not that we have already referred to, but one of somewhat smaller size. Long troughs containing the solution of silver traverse the room. It is foreign to our purpose to enter into the chemical details of electro-plating; but a word is necessary on the means of obtaining the electric current; besides galvanic batteries with large plates, and generally only single couples, which give a great quantity of electricity, without much tension, we find in this room a very powerful electro-magnetic machine, worked by a small steam engine, of very elegant design, fixed at a little distance. The magnetic machine very much resembles that which was exhibited last year in the Machinery-in-Motion Court, at South Kensington. Its current which, though small in quantity, is of enormous tension, is employed for plating spoons, forks, and all articles subject to much wear, as the deposit, when such a current is employed, is of greater hardness than it is possible to procure by any other means. Dish covers, and all articles not subject to so much wear, are plated by the action of the galvanic battery, which, with but a slight reduction of hardness, effects the operation in a much shorter time.

In the two long tanks alone in this room not less than £6,000 worth of silver solution is contained, 10 oz. of solid silver being dissolved in each gallon of the solution. In this room also are two or three small tanks for depositing gold; although containing but a few gallons comparatively, they nevertheless manage to hold about £2,000 worth of gold in solution, which being hot gilds with surprising rapidity. We saw the inside of an egg-cup sensibly gilded in half a minute; two to five minutes generally give a rich coat of gold; five or six hours are required to plate silver articles.

On leaving the baths the articles are brightened by revolving brass wire brushes and ale wort, and are then sent to be planished; in this operation, every article which presents a broad flat surface is hammered all over to condense and harden the silver coating. The remaining processes of burnishing and cleaning present no features of much importance; and as we have already overstepped the limits at our disposal, we must conclude by expressing our thanks for the courtesy shown us by the representatives of a firm, whose importance, even to so large a town as Birmingham, may be imagined when we state that it gives employment to about 1,100 hands, and has branch houses in the City and West End of London; also in Liverpool and Dublin.

Mr. Ansdell's picture, "The Hunted Slave," has been presented by that gentleman to the town of Liverpool.

THE SOILS OF ENGLAND.

On Friday, the 8th inst., Dr. Augustus Voelcker, F.C.S., Consulting Chemist of the Royal Agricultural Society of England, delivered a lecture before the Royal Institution, "On some Chemical and Physical Properties of Soils, and the Productive Powers of the Soils of England."

In all fertile soils, said the lecturer, we find variable quantities of organic matter—ready-formed ammonia, nitric acid, potash, soda, lime, magnesia, oxides of iron, chlorine, phosphoric, sulphuric, and silicic acids; in short, all the mineral matters which are found in the ashes of plants. These minerals, or ash-constituents, it need scarcely be observed, are not merely accidental but essential materials, without a proper supply of which no plant can grow luxuriantly and come to full maturity. In one sense, all are equally important; for the absence or deficiency in the soil of one, be it lime or potash, phosphoric or silicic acid, is detrimental to the luxuriant development of the vegetable organism. No one who has given the slightest consideration to this subject will hesitate to give assent to this mineral theory.

It is natural to connect the productiveness of soils with the proportion of ash-constituents of plants which they contain; but although in some cases a soil may be unproductive on account of the absence or deficiency of lime or potash or phosphoric or any other mineral matter which enters into the composition of plants, in the majority of cases the chemical analysis of different soils affords little or no indication of their relative productive powers.

The combinations in which the mineral constituents of plants exist in the soil, their unequal or uniform distribution in the surface, the composition and physical condition of the subsoil, the relative depth of both, the porosity of the land, and especially the power of absorbing and retaining, as well as modifying in a variety of ways the crude manuring agents which are applied to the land, unquestionably are intimately connected with the great variations which we notice in the agricultural capabilities of different soils.

Before the publication of Liebig's celebrated "Chemistry in its Application to Agriculture," a work which has given the death-blow to the humus theory, the fertility or barrenness of a soil was generally considered to depend entirely upon its physical properties and the presence or deficiency of humus. Soon after the publication of Liebig's writings, scientific men fell into the opposite extreme, and expected the bare chemical analysis of a soil and the ash-analyses of plants would enable them to discover at once the means of restoring the fertility of land, or to improve it by certain purely mineral manuring mixtures, and to grow on it, irrespective of its natural adaptation to the growth of particular crops, any kind and almost every amount of agricultural produce.

These unphilosophical views have rendered agricultural chemistry less popular than formerly, but also more scientific and more directly useful to the enlightened agriculturist.

A new direction to chemico-agricultural inquiries was given about ten years ago by Professor Way's highly important researches on the absorptive powers of soils for manure. Professor Way's investigations originated in an observation of Mr. Thompson, of Kirby Hall, York, who found that soils have the faculty of separating ammonia from its solution.

On passing solutions of ammonia through different soils, Way found that all possess the power of retaining ammonia, some more, some less. He also observed that potash, lime, magnesia, and phosphoric acid are absorbed by all soils to a considerable extent.

Still more important are his experiments, which prove that cultivated soils not only absorb free alkalies and acids, but have likewise the power of separating ammonia, potash, and other bases from their saline combinations.

Professor Way principally operated with simple salts: it may therefore be urged, that it by no means follows, as a necessary consequence, that because a soil absorbs ammonia when a solution of sulphate of ammonia is passed through it, the same absorption will take place when an ammoniacal salt mixed with some dozen other substances is filtered through it.

I therefore operated with complex liquids, and already, in 1857, published several filtration experiments in the Journal of the Royal Agricultural Society.

These and many subsequent experiments have shown that all soils not only possess the power of absorbing and retaining potash, ammonia, phosphoric and silicic acid, and other mineral matters, but also of modifying in the most varied way the composition of complex saline solutions which are passed through them.

The following table shows the results obtained in filtering the same kind of liquid manure through two very different soils:—

Composition of Liquid Manure before and after filtration through two soils from the neighbourhood of Cirencester.

An Imperial Gallon contains:—	No. 1. Calcareous Clay Soil.			No. 2. Ferrugnous Sterile Sandy Soil.

Sulphuric acid	3·94	2·88	— 1·06	— 3·67	— ·27
Carbonic acid, and loss	5·80	11·80	+ 5·80	— 7·90	+ 2·10
	70,000·00	70,000·00		70,000·00	

The preceeding analytical results, amongst other particulars, show:—

1. That the calcareous clay soil absorbed about six times as much ammonia from the liquid manure as the sterile sandy soil.
2. That the liquid manure in contact with the calcareous clay soil becomes much richer in lime; whilst during its passage through the sandy soil, it becomes purer in lime.
3. That the calcareous soil absorbed much more potash than the sandy soil.
4. That the chloride of sodium, in conformity with the results of other observers, was not absorbed to any extent by either soil.
5. That both soils removed from the liquid most of the phosphoric acid.
6. That the liquid in passing through the calcareous soil becomes poorer; and, on the other hand, in passing through the sandy soil, becomes richer in soluble silica.

(To be continued.)

PATENT ICE-MAKING MACHINE.

The *Birmingham Post* gives an account of a very ingenious machine for the manufacture of ice, patented by Messrs. Siebe Brothers, of Mason-street, Lambeth, London, and manufactured by

Mr. W. H. Phillips, of the Atlas Foundry, Oozells-street, Birmingham. The machine has been made for a firm in Banbury, who have now in use one of Messrs. Siebe's machines, which is capable of producing four tons of ice per day. This machine, which is the first of the kind made in Birmingham, is capable of producing ten tons per day, and is driven by an engine of twenty-horse power. The machine has been completed only a few days, and as it was necessary to try it before exportation, it has been used, and the ice manufactured has been bought by Mr. Copner, of New-street, and others. The machine consists of an engine, a large tank, and four longitudinal troughs ot considerable dimensions, and placed side by side. In these troughs the spring water to be converted into ice is placed, in metal vessels about 2 in. wide, and some 2 ft. deep. Brine, containing as much salt as can be held in solution, is forced through the troughs, and runs round the vessels containing the spring water, and when it has run through the whole series it is pumped back into a large tank, and after being again reduced to an intense degree of cold is once more forced through the troughs, and this process is repeated until the whole of the water is converted into ice, which is turned out in slabs of even size and thickness. The degree of cold produced is so intense that the ice begins to form in about twelve minutes from the commencment of the operation. The ice made by the machine is beautifully clear, and not the least of the many advantages of the process is that no chemicals whatever are used. The manufacture of ice in tropical climates is a most important operation, and to this end Messrs. Siebe's machines have been extensively applied, one of them being now at work in Peru, almost under the Equator.

INSTITUTION OF CIVIL ENGINEERS.

May 19, 1863.

John Hawkshaw, Esq., President, in the chair.

The Paper read, was "On the Manufacture of Duplicate Machines and Engines," by Mr. John Fernie, Assoc.Inst.C.E.

After referring to the block-making machinery, designed by the elder Brunel for Portsmouth Dockyard, and to the Small Arms' Factory at Enfield, as examples tending to show that the system of duplicates both cheapened and improved the manufacture of all articles to which it could be applied, the Author remarked that, until lately, little or nothing had been done in its application to the manufacturing of machines or engines on a large scale. It was true the principle had been acknowledged, and various writers had urged the desirableness of its introduction into the railway system; but with such large component parts, special machines were out of the question, and the only other possible mode was working to a correct standard.

Mr. Whitworth (M.Inst.C.E.) had advocated, in several Papers read before different scientific societies, the adoption of a system of measurement for mechanical engineering work, in which the inch was to be the basis, subdivided into a thousand parts for the finer dimensions. In 1851, he exhibited a machine for obtaining fine accurate measurements by touch, and he showed, by models, that the thousandth of an inch was not only an appreciable quantity, but in many cases its difference was what constituted a bad fit.

The Author, having been satisfied that the mode of taking dimensions in the workshop was behind the times, had, with the sanction of Mr. Kirtley, the locomotive superintendent, established during the last five years, in the workshops of the Midland Railway at Derby, a system which had proved most beneficial, not only in reducing the cost of the work, but in greatly reducing it; and at the same time perfecting the only plan by which all the parts of engines could become duplicates of one another. The system of end measurement and a gravity piece, as invented by Mr. Whitworth, was adopted, and a machine was constructed capable of taking in 100 inches. This machine consisted of a strong bed plate, having on the upper surface a V-groove, planed throughout its whole length. At one end there was a headstock, through which a square spindle, fitting the groove, was propelled by a hand wheel, which formed the nut of a screw having ten threads to an inch. This nut was in two parts, and could be tightened up by screws, so as to prevent lateral play; and a collar washer, also adjustable, prevented any play in the headstock. The other end of the bed had also a headstock and screw movement, so as to adjust the length of the pieces in the groove, and bring the readings of the index to O. The difference between this machine and Mr. Whitworth's was in the way the subdivisions of the inch were obtained. In the Whitworth machine a screw with exactly ten threads to an inch was first made; whereas, in this machine, as a screw could not be found with exactly ten threads, it was necessary to run a thread on the face of the hand wheel, and subdivide this for the length required for an inch. The manner of obtaining duplicates with this machine was exceedingly simple. First, a perfect inch was got, and then a second was made, by means of the gravity piece; after which, all other sizes up to 100 in. were readily obtained. These sizes were now kept as duplicates. The finer dimensions were read from the divisions on the wheel, and from these, gauges for use in the workshop were made. All dimensions were thus duplicate multiples, or divisions of an inch, and a bare 1-16th in. became not an unknown quantity, variable with the rule or the eye of the workman, but so many thousandths of an inch, which were stamped on the gauges, and were soon understood. One of the first applications of the system in the workshop was to establish the necessary degree of tension required to ensure a perfect fit of a wheel on its axle. The result of experiments showed that with a difference of ·005 of an inch in the dimensions, there was a small permanent set in the wheel boss, but with a difference of ·003 of an inch the set was hardly perceptible. It was found, however, that, with ordinary lathe work, ·003 was rather too fine a dimension, as lathes were seldom exactly true in their spindles. The size ·005 was then finally adopted. In shrinking on outside cranks it was found that that ·015 was sufficient to retain them in their places, while cross-head spindles 2½ in. diameter required a difference of ·004, and levers with 3 in. holes of only ·001.

The gauges were described, as well as the manner in which the lengths of the eccentric rods were preserved uniform, and how the key groove in the outside cranks and the eccentric key grooves were cut. No setting out was required, and there was no chance of mistake from the carelessness of workmen. Unless the cranks and eccentrics were exact, they would not fit the tools, and thus a certainty was attained in the depth and position of the key groove.

Considerable improvements had been effected of late years in plate moulding, and the plan adopted at the Midland Railway Works at Derby was believed to be the first application of the system to such large and complicated castings as locomotive cylinders. Moulding boxes for axle brasses were exhibited, and a description was given of the manner of moulding cylinders. By this mode, a minimum quantity of sand was used, the projecting pieces cast on the boxes did away with the necessity of lifters, the castings came cleaner from the sand, the patterns were not knocked to pieces by rapping, and the cylinders were perfectly true in the bore and passages.

The plan of fitting together the various pieces, so as to ensure uniformity in erection as well as in detail, was then described; and it was urged, that by this system of accurate measurement, however large the parts might be, they became duplicates of one another, and could at any time be replaced. The advantages claimed were, economy in manufacture, greater excellence in workmanship, and a perfect system of duplicates, whereby the parts became interchangeable. The Author especially recommended this system to the Engineers of Indian and Colonial Railways, as there was no reason why the different parts of engines and of rolling stock generally, should not be as perfect duplicates as those of the Enfield rifle.

INTRODUCTION OF AN IMPORTANT NEW PROCESS INTO SHEFFIELD.

Many of our readers will be interested to learn that M. Simmolet, a French manufacturer, is introducing into Sheffield a new process of manufacturing scissors, which promises to revolutionise some departments of that trade. By the old process scissors are forged by hand. A flat narrow piece of steel of the requisite length and thickness for the size of scissor required is beaten on the anvil with a hand hammer into a rude approach to the shape required. The bow is made by punching a hole through the shank end, and hammering the steel thinner and wider until the requisite width is obtained. The ornamentation of the shank has to be produced by the hand-file—a long, laborious, and therefore expensive process. After all this labour has been expended upon the scissors, they are sent to the grinders to be put into shape. Even the filer leaves the scissors very rough and uneven, and the grinding is consequently a laborious operation. By the new process, a great portion of the labour we have indicated is saved. Commencing with the narrow piece of steel, M. Simmolet first chips slight pieces out of the shank by a single stroke of a machine. Another piece is struck out of the centre of the shank end, and by the simplest process possible—the introduction of a sort of wedge—the hole thus made is enlarged into the bow. Then comes the simple process by which the old plan of forging is superseded, filing is nearly done away with, and the grinders' labour is materially diminished. Dies of the precise size and shape of the scissor required are fixed in a steam hammer. The scissor is placed upon one die fixed on the anvil of the hammer, and is struck with a corresponding die fixed to the face of the hammer itself. By this simple and ingenious process scissor after scissor is forged almost by a single blow. The object of forging scissors is, by compressing the pores of the steel, to impart that hardness, tenacity, and elasticity—in one word, that "temper" on which the value of the scissors, as a cutting implement, depends. We are assured that this result is attained even more perfectly by M. Simmolet's steam hammer and dies than by the hand hammer of the forger. The forger hammering first one part of the blade and then the other, often tempers one part better than the other; but by the use of the steam hammer perfect uniformity of temper is obtained throughout. As a question of temper, the machine-made scissor is at least equal to the one made by hand from the same quality of steel. In every other respect it is superior. In the first place the bows and shanks, as well as the blades, of machine-made scissors are perfectly uniform, and perfect uniformity cannot be secured by the hand hammer, where the workman has to be guided by the eye. In the next place, the ornamentation of the bow is produced by the same stroke that forges the blade. However elaborate the ornamentation required, it has only to be inserted in the die, and is reproduced in perfection in the scissor. Thus the long and laborious operation of filing the straight or slightly curved bow into a highly ornamented one is not only saved, but improved upon. The scissor comes from the machine with a narrow flange on each edge. The greater part of the flange is cut off by machinery, and the hand file is required only to round off the edges from which the flange has been cut. The steel, moreover, comes from the steam hammer a smooth and perfect scissor as regards shape. There is no unevenness of surface to be ground down; only polish and edge is required, and therefore the work of a grinder is obviously much less than in hand-forged scissors. Hand-made scissors have to be made in pairs, and require great care and labour in fitting. But scissors made by these machines are so perfectly uniform that any two taken promiscuously from a heap fit together as a pair without the least adaptation, and M. Simmolet's invention provides for the riveting by a process as simple as its predecessors. The total result is this:—The machine-made scissors are in bow, shank, and blade perfectly uniform; the bows are rounder and smoother inside than those of the hand-forged scissors, and are consequently much more agreeable to the fingers in use; the quality of the blade is equal to that of the hand-forged scissors if the same quality of steel is used; moreover, scissors entirely devoid of ornamentation can be produced cheaper by machinery than by hand; and ornamented scissors can be produced at greatly reduced prices. M. Simmolet's process is already in successful operation in

France, and producing scissors superior in finish and general appearance to those of English make as regards the bows and shanks—the ornamental part. The French grinders are, however, less skilful than those of Sheffield, and French manufacturers cannot equal those of Sheffield in the quality of their steel. English scissors are, consequently, superior in the blade; French scissors, in the bow and shank. By introducing his patent here, M. Simmolet offers Sheffield manufacturers an opportunity of combining all the excellencies of the French and English scissors, without the defects of either, and at a lower price than either. Such are the merits claimed for the new invention. If in the actual result those claims are substantiated, the question obviously arises, can Sheffield hope for any length of time to retain the scissor trade at all, unless her manufacturers, by taking advantage of the new process, put themselves in a position to keep ahead of their foreign rivals? We will now only add that those of our manufacturers who best know the invention believe it to be valuable.—From the *Sheffield Independent*.

BARNINGHAM'S IMPROVEMENTS IN THE PERMANENT WAY OF RAILWAYS.

FIG. 1.

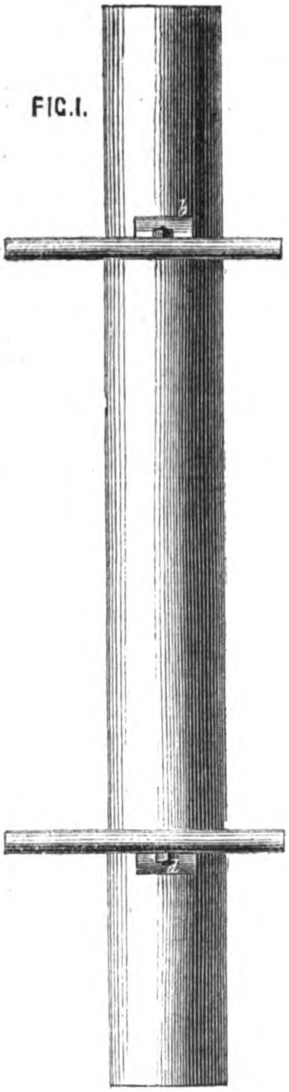

FIG. 3

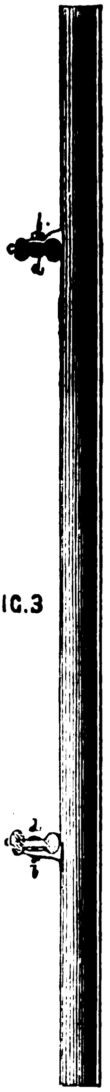

FIG. 2.

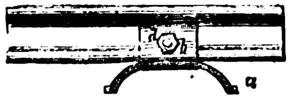

ACCORDING to this invention, lately patented by Mr. Barningham, of Pendleton Iron Works, near Manchester, railway sleepers, either transverse or longitudinal, are made of wrought iron, rolled to a semi-elliptical or other suitable form, to combine strength with lightness, and of sufficient area to be firmly supported on the ballast. The rails are attached by bolts or otherwise to chairs or half-chairs, which are welded, riveted, or bolted to the sleepers, or the chairs may be formed of strips of metal cut from the top of the sleeper on three sides, and bent into the required form to suit the shape of the rail. When bridge or other flat-bottomed rails are employed, they may bear upon, and be connected to, the sleepers by bolts or rivets. Fig. 1 is a plan of the improved wrought-iron sleepers with half-chairs welded thereon; fig. 2 is a side view; and fig. 3, an elevation of the same; *a*, *a*, are the wrought-iron sleepers, rolled of a semi-elliptical form, or semi-circular or other suitable form, to combine strength with lightness, and of sufficient area to be firmly supported on or by the ballast; when the sleepers have been rolled, they are cut off to the required length by a circular saw or otherwise, and they are then ready to have the half-chairs *b* welded to them, rails *c* are secured to the half-chair *b* by the bolts *d*. In welding the half-chairs to the sleeper the upper surface of the sleeper is slightly depressed, so as to form a level surface for the under side of the rail to bed upon, or the sleepers may be rolled with a flat surface on the top.

TANGYE'S IMPROVED DIFFERENTIAL PULLEYS.

FIG. 1.

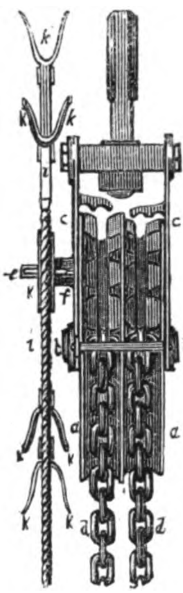

FIG. 2.

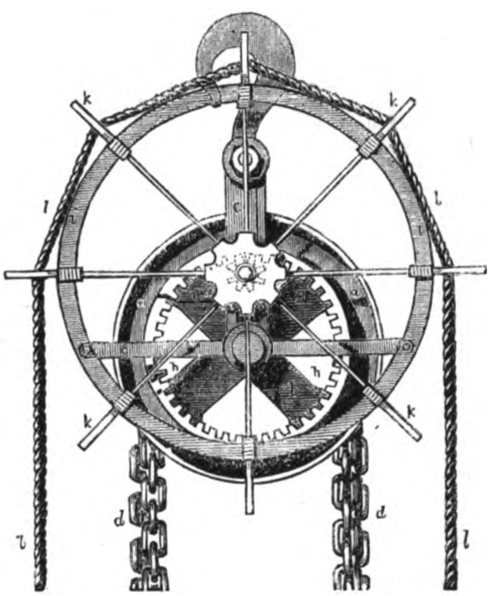

TANGYE'S IMPROVED DIFFERENTIAL PULLEYS.

THE following is a description of an improvement on Weston's differential pulley blocks, which has been lately patented by Mr. Tangye, of Birmingham. Mr. Weston's pulleys were described in the Specification of Letters Patent dated the 25th day of April, 1859, No. 1,033. By the use of the mechanical arrangements hereinafter described, these differential pulleys may be applied to the lifting of heavier weights than they can conveniently be applied to the lifting of as ordinarily constructed. To the axis of the pulley is attached a toothed wheel, with which toothed wheel a pinion on another and parallel axis engages. The axis of the said pinion carries a ratchet lever or winch with which to turn it, or is provided with a spocket wheel with an endless band passed over it for the same purpose. By giving a rotary motion to the axis of the pinion a slow motion is given to the differential pulley. By this invention differential pulleys may be made very powerful, without increasing the size of the pulleys to an inconvenient extent. Although a train of one toothed wheel and a pinion is sufficient for all ordinary purposes, yet multiplying gear consisting of a longer train of toothed wheels may be employed where it is desirable. The toothed wheel and pinion may either work within or without the frame carrying the pulley. Where the pulley is small the toothed wheel may be conveniently made hollow, the pinion taking into teeth on its inner surface.

Fig. 1 represents in front elevation, and fig. 2 in side elevation, a differential pulley, to which said pulley that form of this invention is applied. The same letters indicate the same parts in each figure.

a is the differential pulley turning on the axis *b*, the said axis being supported by the frame *c*; *d* is the looped endless chain of the differential pulley. Eccentric to the pulley, and parallel with its axis, is an axis *e* working in the bearing *f* carried by the frame *c* of the pulley. The axis *e* passes through the frame *c*, and has a pinion *g* on its end, which pinion gears with the teeth of the hollow toothed wheel *h* cast with the differential pulley *a*. Connected with the axis of the pinion *g* is a spocket wheel *i*, on the periphery of which the forks *k* are situated, between which forks an endless band or rope *l* is passed. By giving motion to the endless band or rope *l*, the spocket wheel *i* is made to rotate and communicate motion to the pinion *g*; the said pinion *g* gears with the toothed wheel *h*, and gives a slow rotary motion to the differential pulley *a*. Instead of the spocket wheel *i*, by which the axis of the pinion *g* is turned, the said axis of the pinion may be provided with a ratchet lever or winch with which to turn it. Although it is found convenient, in the case of pulleys of small diameter, to make the pinion gear with a hollow-toothed wheel inside of the pulley, yet the said pinion may gear with a toothed wheel the teeth of which are formed on the periphery of the pulley; or the said pinion may gear with a separate toothed wheel fixed on the axis of the pulley. In this last case, it is preferred to place both the pinion and toothed wheel outside the frame carrying the differential pulley. Instead of making the pinion on the axis which carries the spocket wheel, or ratchet lever, or winch, gear directly with the toothed wheel of the differential pulley, multiplying gear may be placed between the pinion and toothed wheel of the differential pulley.

SCIENCE EXAMINATION OF THE SCIENCE AND ART DEPARTMENT OF THE COMMITTEE OF COUNCIL ON EDUCATION.

THE annual May Examinations of the Pupils of Science Schools and Classes by the Department of Science and Art have just terminated, and the result shows a very satisfactory increase in the number of centres of examination, and the number of pupils who have come up to be examined; although in some subjects thete has been a decrease as compared with last year. In Geometrical Drawing the number of pupils examined in 1862 was 119, but this year they have increased to 289. In Machine Drawing the number has increased from 70 to 194; and in Building Construction there has been an increase from 45 to to 107. In Theoretical Mechanics there has been a falling off from 52 pupils to 35, and in Applied Mechanics the decrease is from 47 to 22. The Experimental Sciences appear the most popular. In Acoustics, Light, and Heat there is an increase from 47 to 121; and in Magnetism and Electricity the increase is from 105 to 207. Inorganic Chemistry shows an increase from 558 to 579; and Organic Chemistry an increase from 105 to 157. It is rather remarkable that there should be a falling off in some of the Natural Sciences. The number of pupils in Geology has decreased from 189 to 129, and in Mineralogy from 81 to 46. There is a slight decrease in Animal Physiology from 349 to 343; but in Zoology the decrease is from 84 to 41. In Vegetable Physiology there is an increase from 66 to 126, and in Systematic Botany from 26 to 84. In Mining and Metallurgy, which has been lately added to the list of subjects, there were 29 pupils in the former and 63 in the latter. The centres of examination have increased from 54 in 1862 to 71 in 1863; and the number of pupils examined in the different subjects has increased from 1,943 to 2,762. These figures only give an approximate estimate of the number of pupils receiving instruction in Elementary Science because a considered proportion are not sufficiently advanced to attend the examination.

South Kensington Museum, May 26, 1863.

MANCHESTER ASSOCIATION FOR THE PREVENTION OF STEAM-BOILER EXPLOSIONS.

At the last ordinary monthly meeting of the Executive Committee of this Association, held at the Offices, 41, Corporation-street, Manchester, on Tuesday, May 26th, 1863, Mr. L. E. Fletcher, chief engineer, presented his Monthly Report, of which the following is an abstract:—

During the past month, there have been examined 257 engines—1 specially; 420 boilers—10 specially, 11 internally, 77 thoroughly, and 322 externally, in addition to which one of these boilers has been tested by hydraulic pressure. The following defects have been found in the boilers examined:—Fracture, 8 (3 dangerous); corrosion, 22; safety-valves out of order, 1; water gauges ditto, 11; pressure gauges ditto, 6; feed apparatus ditto, 2; blow-out apparatus ditto, 3; fusible plugs ditto, 1; furnaces out of shape, 2 (1 dangerous); over pressure, 2 (both dangerous); blistered plates, 2 (1 dangerous); total, 60 (7 dangerous). Boilers without glass water gauges, 2; without pressure gauges, 5; without blow-out apparatus, 17; without back pressure valves, 34.

The occurrence of explosions during the past few months has been so frequent, that the reports of their details have prevented any notice of the defects found to exist in the boilers under inspection, further than that given in the monthly lists as above; and, therefore, the present opportunity may be taken for some slight amplification.

Serious cases of corrosion continue to be met met with at the bottom of those boilers which are set upon brick mid-feathers, running underneath them from one end to the other along the centre or keel line. In this mode of setting, any water which may fall upon the boiler, or leak from the seams, trickles down the shell, and settles on the top of the mid-feather, in contact with the plates. Also were damp exists in the flues, it easily rises through the mid-feather and reaches the boiler. Corrosion may be going on along the centre of the mid-feather and not be visible at the sides, and thus pass undetected even on careful examination—several instances of which have recently been met with.

In one case, a boiler, 10 ft. 5 in. in diameter, and of plates 7-16ths thick, was found, upon the removal of the brickwork, to be deeply channelled for a width of 6 in. along the bottom at the centre of the seating, no indication of which was given at the sides of the wall, nor was it detected by hammering internally, but remained unknown until the removal of the brickwork. In another boiler, the shell of which was 8 ft. 2 in. diameter, and ⅜ in. thickness, the plates were found to be channelled longitudinally along the centre of the mid-feather for a width of 8 in. The seating was 15 in. wide, and the channel died out at 3 in. from the outside, thus giving no external sign. In a third boiler, the flues of which were damp, the whole of the plates in contact with the mid-feather were found to be corroded and as much as a quarter of an inch in thickness eaten away. Other instances might be adduced, but the character of the injury is so similar in each case that it would be tedious. Those already given will show the grounds upon which the following recommendations are made:—

1. Wherever it is practicable to do so, dispense with mid-feathers altogether, and substitute what are termed two side walls for them. 2. In those cases where the small size of the boiler forbids this, make the bearing surface of the mid-feather wall as narrow as possible. 3. Any that must be retained in use, should, in preparation for annual "thorough" inspection, be removed—at least where in contact with the transverse seams of rivets—in order to admit of complete examination.

Further cases of corrosion may be mentioned occurring to other boilers than those set upon mid-feathers.

A tubular boiler, without any external flues, was found so deeply channelled at the bottom of the shell at the transverse seams of rivets, that the plates were reduced to the thickness of a sheet of paper, and a hole knocked through them in sounding their strength with a hammer. A second boiler, of ordinary double furnace, internally-fired construction, was so eaten away by corrosion at the first bottom plate from the front, that, as in the preceding case, a hole was made on examination; the corrosion being due to leakage from the glass water gauges, and mudhole joint, as well as to the practice of slacking the ashes while lying at the front of the boiler. In another case, where the cross wall below the front end of the boiler was as much as two feet in thickness, the plates were corroded nearly through. So great a thickness as 2 ft. for these walls is quite unnecessary, as well as objectionable, and it is recommended that they should be removed periodically for the examination of the plates.

Several cases have been met with during the past month of injury occurring to externally-fired boilers at the parts immediately over the furnace, the plates bulging, cracking at the rivet holes, and the seams straining and leaking. One of our members has contributed a sample plate cut out from a boiler of this class, which is bulged down at the solid, and cracked completely through, although the boiler was amply supplied with water; this plate is a fair sample of the danger of the externally-fired class, and lies at the office for the inspection of members.

A safety-valve, the spindle of which passed through a bushed hole in the cover, was found to fit so tight as to be quite fast. This bush had been fitted to prevent the inconvenience arising from the escape of steam, under the impression that a safety valve was unnecessary, as long as the boiler was provided with a steam pressure gauge.

Explosions.—A report relative to Explosion No. 9, recorded in the last month's abstract, has since been received from an engineer who examined the boiler shortly after the explosion had occurred, and from which it appears that the boiler, which was of plain cylindrical egg-ended construction, and externally-fired, had rent—as is so constantly found to be the case in this class—at the transverse seams over the fire, the shell dividing into two parts, which were thrown some distance asunder. One boiler only, and which was not under the inspection of this association, has been reported to have exploded during the last month; the explosion occurring at too great a distance from Manchester to admit of a personal investigation. Should any particulars of interest be ascertained, they will be communicated in the next monthly report.—The explosion will rank as No. 10 in this year's list.

Up to the 13th of last April no less than 7,402,339 gallons of petroleum had been shipped from New York to foreign ports. London and Liverpool are the two great receiving ports of American petroleum—over 1,000,000 gallons having been sent to each of these places at the date stated. In addition to the above, 3,353,608 gallons have been shipped from Portland, Boston, Philadelphia, and Baltimore, making a total of 10,755,947 gallons. The petroleum trade with foreign nations has already attained to gigantic proportions.

PALSER'S PAPER PULP APPARATUS.

The improved machinery for manufacturing paper pulp, illustrated on the next page, has been recently patented by Mr. J. B. Palser, of Holborn. The object of this invention is to reduce straw and other fibrous materials to pulp in an economical and expeditious manner. The process may simply be described as the subjecting of straw and other fibrous materials to to the action of an alkaline solution in rotating boilers, under the pressure of from 110 lb. to 130 lb. to the inch or thereabouts.

In the accompanying engravings, fig. 1 represents a sectional elevation, and fig. 2 a partial section, of the apparatus employed in carrying out this process.

A, A, is a reverberatory furnace for supplying heat to a pair of cylindrical boilers B, B, which are intended to receive the stock or material to be operated upon, and are capable of rotating on their axes. The boilers are mounted in separate compartments, constructed of brickwork, and communicating by means of separate flues, with the furnace A. Above these boilers, and supported by the walls of the compartments, evaporating pans or vats E, E, are mounted, which are respectively brought into communication with the boilers by means of a suitable arrangement of pipes, to be presently described. The pans E, E, are intended to receive the alkaline liquor which has been used in the treatment of the fibrous materials, and to assist (by evaporating the watery particles) in the recovery of the alkali. The bottoms of the pans E, E, are pierced with holes at suitable distances apart, and these holes are capable of being closed by plugs, the plugs in each pan being attached by chains to arms carried by a rock shaft *a*, which has its bearings on the ends of the pans. These holes are intended to discharge the liquid from the pans on to a hearth below the boilers, allowing it in its passage to flow over the rotary boilers, and thereby utilizing the surface heat of the boilers. The rock shafts are weighted, as shown at fig. 2, to ensure their retaining the position into which they are rocked. Within the division wall of the chambers a longitudinal passage or flue is formed. This flue is employed for heating air, which is forced therein by a blowing engine, and is led off thence in a heated state by a pipe at the other end of the flue to branch pipes. These branch pipes conduct the air upwards into the vats or pans, and discharge it into the liquor contained in the pans through a number of small holes made in the portions of the branch pipes which lie on the bottom of the vats. By the discharge of air into the vats, the evaporation of the liquor contained therein is materially accelerated. Through the flue a water pipe *e* passes, which leads from a reservoir of water, or it may be alkaline liquid, placed on a higher level than the boilers, the object being to heat the liquid on its passage to the boilers. The pipe *e* on its exit from the flue is divided into two branch pipes, which turn respectively into one of the boilers through fixed hollow stud axles on which they are mounted. At the opposite end of the boilers to that at which the branch feed pipes are situated is an arrangement of steam pipes *f*, *f*, connected with the hollow fixed axles of the boilers, for the purpose of conveying steam thereto, either from an adjacent steam boiler or from one boiler B to the other, according to the stage of the process at which the steam pipes are brought into use. These pipes are fitted with faucets for changing at pleasure the direction of the flow of the steam. The axles are divided longitudinally by a partition, as shown in the enlarged sectional view, fig. 3 and leading from these passages, near the inner and closed ends of the axles, are lateral pipes, as shown. These pipes, are intended for supplying their respective boilers with or exhausting them of steam, and also for withdrawing the liquid therefrom. The pipes, which extend to the lowest part of the boilers, form a vent for the liquid at the end of the process for preparing the pulp, the liquid being forced out through them by the pressure of the steam in the boiler and discharged into the vats above, or the liquid may be otherwise directed as thought desirable. The pipes for discharging the liquor and admitting and discharging steam are separated from the "stock" in the boilers by vertical perforated partitions *g*, and thus they cannot be broken or even bent by the pressure of the revolving "stock," nor can they be closed by solid matters accidentally forced into them. The partitions serve also as strainers for retaining the "stock" in its own compartment, and yet permit the drawing off of all the liquid matters at any desired time during the operation hereinafter to be described.

In order to economize to its full the heat of the reverberatory furnace, the liquid is discharged from the pans alternately, by means of pendent pipes on to the boilers. Dampers are provided for closing the flues, and thus diverting at pleasure the course of the gases of combustion from the furnace to the boilers. These dampers can be alternately raised and lowered, in order that the heating of one boiler may be proceeding while the other is cooling.

When straw is the material to be operated upon, it is first cut into suitable lengths, subjected to a winnowing process to cleanse it from dirt, and then crushed between a pair of iron rollers. The straw thus prepared is ready to be acted upon in the above apparatus. Supposing one of the boilers to have been emptied of its contents while the operation of boiling under a high pressure was proceeding in the other boiler, and that this boiling is just completed, things are ready for a repetition of the operation, which is conducted as follows:—The empty boiler is filled with the prepared straw or other substance through a man-hole *k*, and the man-hole is then closed. A solution of caustic alkaii, of a strength indicating from 3½ deg. to 3¾ deg. Beaumé, is next run into the boiler in the proportion of about 60 gallons of the liquor to every 100 lb. of the cut straw, and the boiler is set in rotary motion by means of suitable driving gear connected with the spur wheel *l* affixed to the outer extremity of the boiler. The fire heat is now cut off from the adjacent boiler by dropping its damper, and admitted by the raising of the other damper to the boier last charged with fibrous material. Steam from the heated boiler is also turned into it until the temperature and pressure are equal in both boilers. This operation is important, as the means of raising the temperature in the one boiler is expedited, while the cooling of the other boiler is also facilitated.

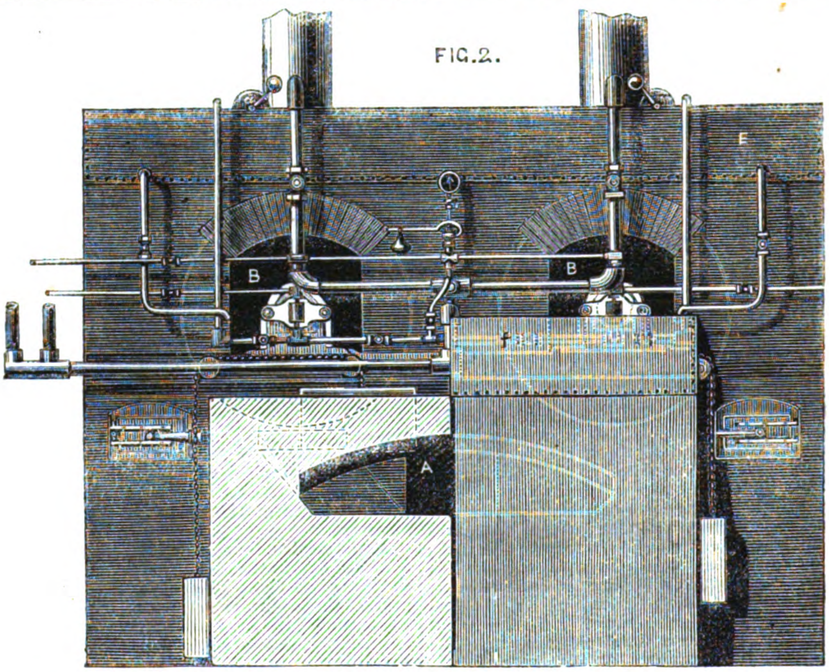

FIG.2.

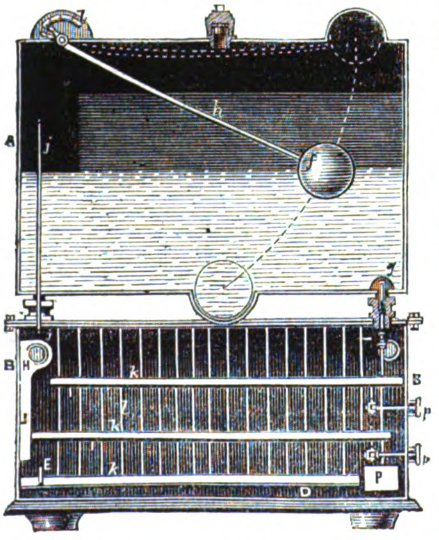
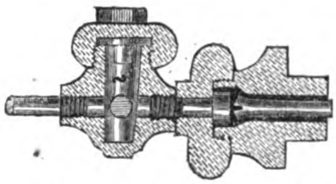
BROOMAN'S CARBURETTING GAS APPARATUS.



THIS apparatus, recently patented by Mr. Brooman, on behalf of Messrs. Bricout and Berlet, of Reims, France, may be divided into three parts, consisting—1, of a vessel or reservoir for containing the carburetting liquid; 2, of the carburator proper, fed by the first-named vessel; and, 3, of certain valve and tap arrangements, all as hereafter described.

A is the vessel or reservoir for containing the carburetting liquid, and B is the carburator proper. The reservoir A is placed above, and is independent of the carburator B, and can be removed from it to be supplied with liquid. The reservoir A consists of a vessel, by preference of zinc, with an aperture at top for the introduction of liquid, which is hermetically closed by a capsuled stopper. The reservoir A is supplied with carburetting liquid, as required, by a portable reservoir put in communication therewith by the aperture. The reservoir communicates at bottom with the carburator B by means of a tube, the mouth of which is covered by metallic cloth *g*, to filter the liquid as it flows out. The reservoir is supported on feet, which rest on the carburator. There is an air tube *j*, leading from the carburator B to the reservoir A, passing when the latter is fixed to the carburator, by preference, through one of the feet, and extending to near the top of the reservoir, but when the reservoir is not attached to the carburator, the air tube *j* is replaced by a gas-pipe. The carburator B is supplied with liquid from the reservoir A by means of the tube and a valve arrangement, hereafter described. It is divided by partitions *k*, *k*, *k*, into three compartments, each of which forms a small vessel, the depth varying according to the size of the apparatus. These vessels are fitted with cotton wicks *l*, extending vertically the whole depth, or nearly so, of the apparatus. In the two upper compartments the level of the liquid is regulated by two small tubes, which into the lower vessel. There is a safety compartment D at the bottom of the carburor, at which, carry the overflow from one into the other, and through a tube E, receives any excess of liquid that may be produced. The gas, after having passed through a tap of peculiar construction, reaches the carburator B through a pipe H, and descends by another pipe I to the lower part, where, after having traversed in a zig-zag direction the three compartments fitted with wicks, and thus becoming enriched, issues from the apparatus by another pipe K provided for that purpose. To empty the carburator B, first open the interior tap or taps below the upper vessels, by means of the buttons *p*. When two taps are employed, as shown in the drawing, each of the the vessels *k*, *k*, is provided with a tube. When only one tap is employed, it is furnished with two apertures, each leading to one of the said vessels. The valve arrangement is composed of three principal parts: a tube, a tap, and a valve. The tube is connected to the reservoir A, and terminates in an enlarged head, fitted so as to hermetically close the valve chamber; the tube is fitted at its upper part with a tap *s* (see the detached view), which must be closed whenever the reservoir A is removed. The valve proper is formed with a conical head fitting into a conical seat; the conical head is formed on a rod screwing into a spring *v*, which exerts a strong pressure from top to bottom, and thereby keeps the valve closed. A weighted float P, connected to a lever free to oscillate upon a fixed point, imparts to the valve an upward motion, and exerts sufficient power to overcome the resistance offered by the spring *v*, whereby the valve is opened, and passage is allowed to the carburetting liquid until a certain level is attained in the vessels *k*, *k*, in the carburator B, then the float in rising ceases to keep the valve closed, when the spring *v* acts to keep it on its seat, and thereby closes and stops communication between the carburator B and reservoir A. In order to show the quantity of carburetting liquid contained in the reservoir A, a float is used for indicating the level of the liquid in the reservoir. The rod *h* of a float *f* is attached at its extremity to a pointer in front of the indicator.



HUMPHRYS' IMPROVEMENTS IN STEERING APPARATUS.

Mr. Edward Humphrys, of Deptford, has lately patented some improvements in steering apparatus, and his invention consists in so combining apparatus for acting by hydraulic power on the rudder of a ship or vessel that the hydraulic cylinder and other apparatus intermediate of it and the rudder may be all below the line of flotation, and consequently out of the way of shot. For this purpose an arm or projection is fixed to the rudder sufficiently below the water line to protect it from shot. This arm is suitably connected to the piston rod of the hydraulic cylinder, which is also situated below the water line of the ship or vessel. A stuffing box is formed through the stern of the ship or vessel for the passage of the piston rod or of a connecting rod, so that the communication between the piston of the hydraulic cylinder and the rudder may be water-tight. The arrangement for working the hydraulic pumps and apparatus may be according to the means at present in practice or otherwise. Fig. 1 shows a side view of the rudder and part of the sternpost of a vessel, the rudder being combined with hydraulic apparatus; the hydraulic apparatus in this figure is shown in section. Fig. 2 shows a horizontal section of the same, the section being taken through the centre of the hydraulic cylinder. In the arrangement shown in the drawing, the rudder *a* has fixed to it an arm *b*, the arm being sufficiently below the water line to be protected from shot; this arm is pin-jointed to one end of a connecting rod, which at its other end is pin-jointed to a cylindrical slide *c*; this slide can traverse to and fro in a guide tube *d*, lined with brass; the cylindrical slide *c* is also pin-jointed to the end of the piston rod *e* of a hydraulic cylinder *f*. The piston rod *e* passes out of the end of the guide tube *d* through a stuffing box *g*; one end of the guide tube *d* passes through the skin of the vessel, and the flange of the guide tube is bolted thereto; its other end is supported from the deck *h*, upon which the steersman who works the hydraulic apparatus stands. In the arrangement of hydraulic apparatus shown in the drawing, water under pressure can be admitted to either side of the piston by moving the slide valve *i* by means of the lever *k*. This is an arrangement now well understood, but other arrangements of hydraulic apparatus may be employed in place of it.

In ships built with very low overhanging "counters," in place of passing the piston rod of the hydraulic cylinder through a stuffing box, as above described, the spindle of the rudder may be passed through a stuffingbox packed in the usual manner to make it water-tight, and the hydraulic cylinder together with the parts connected with it is then placed above this stuffing box, but still below the line of flotation of the vessel, the piston rod of the hydraulic cylinder being by preference connected by a connecting rod directly with an arm on the rudder spindle.

HUMPHRYS' IMPROVEMENTS IN STEERING APPARATUS.

FIG. 1.

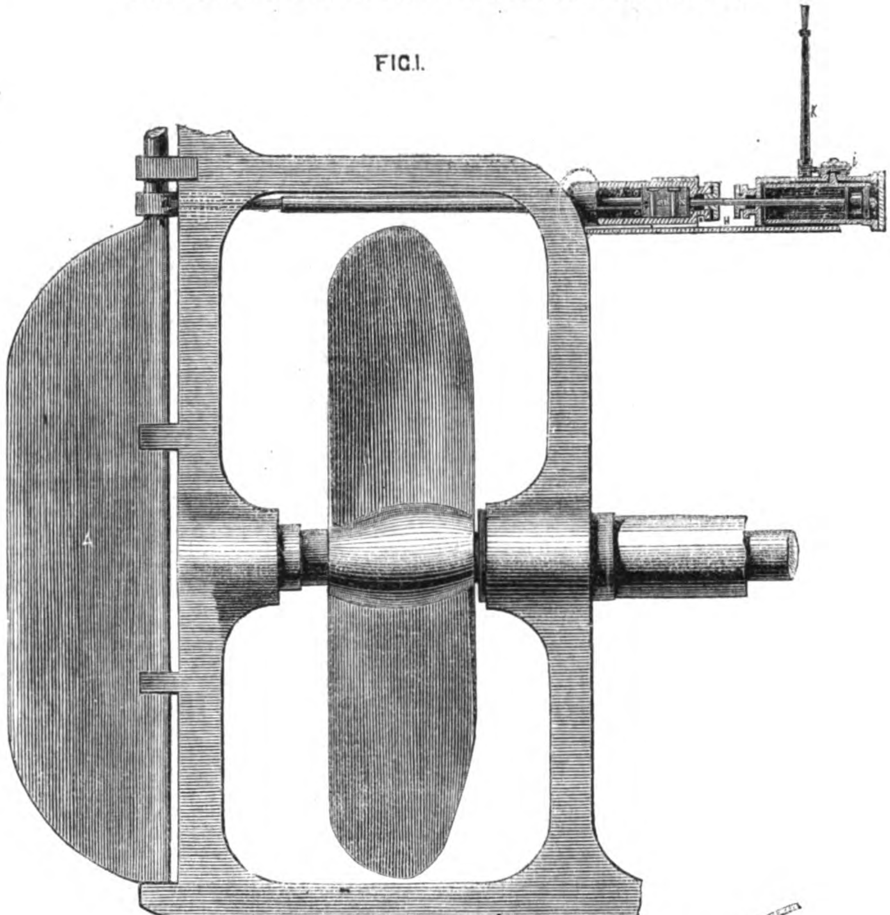


FIG 2.

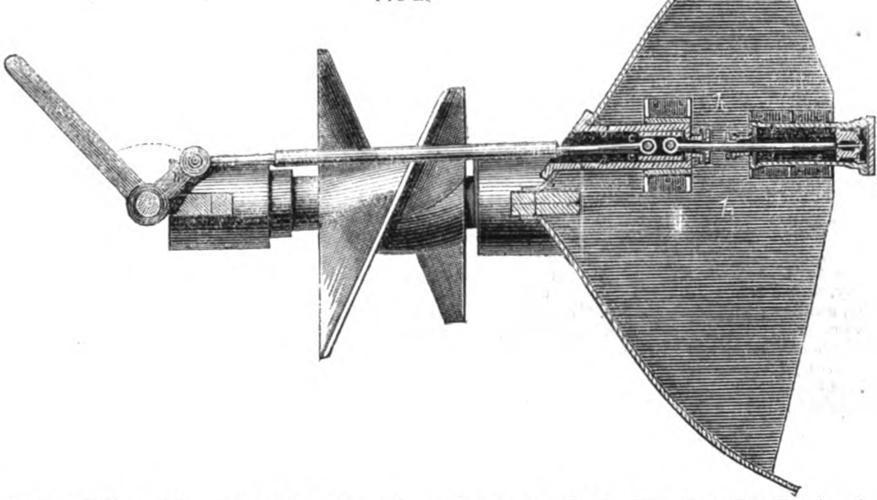

California Flax.—The editor of the Los Angeles *News* has been furnished by Dr. Osborn, of that place, with a parcel of native flax, which grows wild and is said to be abundant in that section. The *News* says it is from a stock which appears to be a species of nettle; in texture there appears to be no material difference between it and common flax. It is thought that this plant might be successfully cultivated. The fibre is quite as fine and strong as a cultivated article of real flax.

Some ingenious German has invented a paper cup which will completely hold a draught of the hottest liquid, and can be bought for a *pfenning*. By means of this invention the good people of Berlin take up and drink at their ease, as they go along the railroad, the cups of coffee which the comfort-loving Englishmen find it impossible to swallow without scalding their throats.

Meetings for the Week.

MON.—*British Architects.*—At 8 p.m.
United Service Inst.—I. "On Naval and Military Signals," by P. H. Colomb, R.N. II. "On the Swords of the International Exhibition," by John Latham, Esq., at 3.30 p.m.
Royal Inst.—General Monthly Meeting, at 2 p.m.
TUES.—*Inst. Civil Engineers.*—President's Annual *Conversazione*, at 9 p.m.
Royal Inst.—"On Sound," by Prof. Tyndall, at 3 p.m.
WED.—*Soc. of Arts.*—"On the International Exhibition of 1862," by William Hawes, Esq. H.R.H. the Duke of Cambridge, K.G., will preside at 8 p.m.
THURS.—*Royal Soc.*—Election of Fellows.
Chemical Soc.—At 8 p.m.
Linnæan Soc.—At 8 p.m.
Antiquaries.—At 8.30 p.m.
Royal Inst.—"On Geology," by Prof. D. T. Ansted, at 3 p.m.
FRI.—*United Service Inst.*—"Telescopes and Opera Glasses for use in the Field or at Sea," by Alex. Strange, Esq., at 3 p.m.
Royal Inst.—"On the Alps of Savoy," by J. Ruskin, Esq., at 8 p.m.
Architectural Exhibition.—Class of Design—Public Memorial.
SAT.—*Royal Soc.*—"On Electric Telegraphy," by Prof. W. Thomson, at 3 p.m.

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisments.

All communications should be addressed to the EDITOR, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

RECEIVED.—F. R.—S. H.—R. T.—V. P.—J. H. P.—S. T.—Capt. S.—B. C.—W. R. T.—W. R.—J. H.—S. and Bros.

PHILO—Thanks. Want of space compels us to decline inserting any more letters on this question at present.

Correspondence.

[*We do not hold ourselves responsible for the opinions of our correspondents.*]

◆

MALLET'S FOLLY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—In your impression of the 15th inst., p. 361, I remark an article under the above title, copied apparently from a Dublin newspaper, the *Freeman's Journal*, which commences thus:—"One of the most promising (prominent is meant, perhaps) objects in or near Dublin was Mallet's Folly—a huge, oblong building, standing upon the north bank of the Royal Canal. It was built by an Irishman named Mallet, who signally failed in his speculations. Since then Mallet's Folly has been falling into decay, and for a long time has been the home of bats, swallows, and ivy. Messrs. Murtagh Brothers have recently restored the building in a most remarkable manner, and what was known as Mallet's Folly is now known as the North City Flour Mills."

The remainder of the article appears to be an advertising "puff oblique," in the usual "penny-a-line" style, and without any obvious interest to your readers.

My father, Mr. John Mallet, is no doubt the person libelled in the paragraph I have quoted; and, as your respectable pages have given currency to this most causeless and disreputable calumny, of an old gentleman now in his 84th year, I presume you will permit me to contradict it by affirming that everything having reference to my father, or to any one of our name, in the article in question, is absolutely false; indeed, the above paragraph contains a separate falsehood in almost each line.

My father is not an Irishman—nor is there Irish blood in any one of our name. He was never a speculator. So far from having signally failed in his transactions—he went to Ireland from Devon in 1800, and, for nearly fifty years, is well known by numbers now living, to have been one of the most prosperous traders and respected citizens of Dublin, one of the easiest proofs of which is that he expended above £10,000—every shilling of which came from the profits of his business—upon the concern referred to.

"Mallet's Mill" was the name it popularly bore; it was never known as "Mallet's Folly." The building had never fallen to decay—the "bats, swallows, and ivy" are simply items of decorative mendacity—having been raised to its full height and roofed in only in 1848 (as the date graven on its stones proves), so it was not "restored in a remarkable manner since."

My father's original destination for it—a rolling mill for lead—having been changed by circumstances affecting that trade with which I need not trouble you, the floors were purposely not completed. The premises, however, were occupied and worked, by the late firm of John and Robert Mallet for several years prior to 1852 as a large forge and iron foundry, auxiliary to their other works, and from them, nearly the whole of the permanent way (except rails) of the Great Southern and Western, the Midland, the Belfast and Ballymena, Ulster, and the other Irish lines, as well as great quantities of other railway plant, were turned out.

The concern, then the joint property of my father and myself, and perfectly unencumbered, was, by our direction, sold some two or three years ago, after we had thought proper to break up all our manufacturing establishments in Ireland. Some one of the name of Murtagh, in the flour trade, was, I believe, the purchaser.

"The moral" drawn with proverbial inconsecutiveness, from this libellous puff, concludes in these words:—"It will teach a lesson to all Irishmen to be self-reliant, true to themselves and to one another, and to leave no Mallet's Folly at which the finger of the scorner can point."

Self-reliance and truth are certainly rare virtues in Ireland—few, however, here at least, will deem the former evinced by newspaper puffing based on calumny, or the latter promoted by lying. None but those who have had opportunity of knowing intimately the social inner life of that country will guess, that it is probably to the facts that my father is English, and dwelling in Ireland in troubled times, never forgot either his allegiance or his Protestanism, and that, while High Sheriff of Dublin, it was his duty to conduct O'Connell to gaol for sedition—that the *animus* of the ultramontane *Freeman's Journal* scribe has thus taken occasion to libel him.

I regret to have had to occupy your pages with matter of so little import to your readers.

Yours obediently,
ROBERT MALLET, M.I.C.E.
The Grove, Clapham-road, London.
May 25, 1863.

[We are sorry that anything which appeared in our pages should have been incorrect, or should have in any way wounded the feelings of Mr. Mallet. The *Freeman's Journal* was our authority for every statement we made.—ED. M.M.]

ELASTICITY IN THE BACKING TO ARMOUR PLATES.

SIR,—I have read with interest the account in your last week's publication of Mr. George Clark's system of iron cellular backing to armour plates. This is the system which your correspondent "Civilian" approves, and I suppose there exists the very best of reasons why it should meet his approbation; but, however that may be, as being founded professedly on the principle of rigidity, it coincides exactly with the views long advocated by him in your pages. We are now enabled to understand what is meant by that principle, both by the theoretical explanation given of it, and by its practical illustration; but it is astonishing to find that in neither of these aspects does rigidity mean rigidity, but elasticity after all. It seems that, without knowing it, there has been all along a deal of prose spoken under the illusion of an inspiration in the poetical vein.

We often meet with bad practice in connection with good principles; but here is an instance, more rare, of a good practical contrivance (barring one important exception, however) in connection with, and supposed to be an illustration of, a false principle. But that one exception is really in accordance with the assumed principle, and therefore spoils the whole affair—I allude to the position of the grain of the timber occupying the longitudinal cells, it being placed "end on." If Mr. Clark had arranged the timber, and of course the grain of the wood lengthwise, he would have added all its strength to the efficiency of his backing; but then he would have adopted Mr. J. Chalmers' plan, and, worse than all, he would have acknowledged the principle of elasticity and repudiated the darling fallacy of rigidity. And yet he would not more pointedly have committed himself—his inconsistency would not have been more glaring than it is already in adopting an iron cellular system for a backing, of which the purport is, he says, and says truly, to introduce "cohesion in every part of the structure," in order that "the projectile force meeting with no adequate resistance from the wood might be dispersed over an extended area, as it would be," he continues, which, however, is a *non-sequitur*, "if complete rigidity were maintained all over and through the structure." The correct sequence would have been, "as it would be in proportion to the extent in which the cohesion is maintained, in virtue of the range allowed to the elasticity in the structure." This explanatory admission, that the efficiency of the iron cellular system consists in a more extended area of resistance, necessarily lets in the principle of elasticity; for how can there be an extension beyond the area of impact of the shot, except through the medium of cohesion and the elastic force, these two standing also in the relation towards each other of the one being effect and the other cause?

It is the yielding of the part struck by the non-penetrating shot, or rather the part immediately under, which brings the cohesion and elasticity of the backing into play, and so makes all the surrounding parts contribute to the total resistance. If that part were perfectly rigid, that is immoveable, it must bear the brunt of the force of impact by itself, for "a dispersion over an extended area" is a physical impossibility unless it does move, and so induces motion all around, else no other cohesion will be concerned but that of the part itself. The implication of other cohesions is the function of elasticity, which can come into operation only through the medium of motion, either in the way of compression or extension. Elasticity manifests itself in a continuous cohesion of the molecules of matter, notwithstanding separation through small intervals of space; but that continuity is likely to be abruptly severed by a concentration of the action wholly upon the molecules immediately concerned, if a distance be not permitted over which the force can act by bending the material, and in so acting accumulate against itself the successive resistances of enlarging circles of cohesion. Thus it is, that, in this case at least, motion and elasticity are correlatives, and that motion and not rigidity is necessary for the development of strength. It may deserve remark here, by way of explanation, that resilience, which generally attaches to our idea of elasticity, is not necessarily an element thereof, it being simply a proof of the elastic force being uninjured by the violence of the impact. This force may be destroyed, but it opposes resistance to destruction; and therefore, though wood and iron may be crippled and deprived of resilience, we can still discuss about elasticity in its development as a force.

The simple fact is, that Mr. George Clark has substituted the elasticity of an iron structure for that of a timber one; and "Civilian" has confounded the greater intensity and smaller range of that elasticity with rigidity. In truth, there is no such thing as rigidity apart from elasticity, in any physical conception of it. It means a certain form of elasticity, in which the force of cohesion is great, and the distance to which it extends is small. Now it is competent for Mr. Clark and "Civilian" to contend, that the elastic force answers the purpose of backing better in the form in which it exists in iron, than in that in which it exists in wood, but by repudiating elasticity in principle, and therefore *in toto* if possible, they have fallen into this absurdity, that whilst actually employing wood, they have refused to appropriate its elasticity, and all the while have availed themselves of the elasticity of iron! Whether the one or the other is the best for the purpose is at present an open question, but I am inclined to think that a union of the two would be better than either separately. Such is the velocity of projectiles, that wood alone appears to be crushed to some extent, as well in the propagation of the blow as in the passage of the shot, before motion can be communicated to, and assistance received from, surrounding parts to any extent that would render available more than a small portion probably of their elasticity. A combination of iron with the wood would materially prevent the crushing, and give time for elasticity to have some degree of fair play; whilst the elasticity of the iron itself in a cellular arrangement, but which I do not think is the best, would be more efficient in point of range than in the armour-plates, by reason of a looser structure and a greater latitude of movement. The rigidity, or stiffness of elasticity, belonging to armour-plates, exposes them to a severe trial, first to resist penetration, and next, if successful in that, to prevent fractures, which will occur, not only in themselves, but in the rigid framing behind. To give them the best chance, would be not to let them have any backing at all, if that were practicable, but to combine them all into one shell, which may be either external to, or constitute the hull of the vessel; elasticity would then have some little scope for fair play. It is quite certain, in point of principle and mere theory, that in the case of a shot impinging on a surface, opposing at first only a slight resistance but a gradually ,increasing one throughout the recoil, such surface, whether of wood or of iron, need scarcely be penetrated at all; but practically, we cannot of course even approximate toward such a result. Such, however, is the principle, and it is false theory and unsound practice to run counter to it.

Yours, &c.,
Benjamin Cheverton.

P.S.—There was a typographical error in my last, of "this" for "thus," which materially injured the sense.

OCEANIC TELEGRAPHY.

Sir,—That combat is hardly a fair one, in which one party is defended by the impenetrable mail of an anonymous signature, while the other throws bare the breast of an unpretentious patronymic open to the attacks of his mailed adversary. I have, indeed, some doubts whether I might not say "scaly adversary," for only the man who, as the ballad has it, "was married to a mermaid," or has some such scaly connections, could justly assume the tone with which "H. K." rebukes me for not saying "I know," instead of "It is probable," when speaking of the bottom of the sea and the oceanic currents. If this be the case—if "H. K.," besides being what seamen call a land shark, has also the intimate knowledge of the recesses of the ocean, generally supposed to be the sole attribute of the sea sharks and their congeners, let him not lose a moment in proclaiming it, and I am sure that all seamen will at once resort to such an authority as we shall then acknowledge him to be.

But if, on the other hand, like a limpet, he has all his life stuck to the rocks of prejudice, and is quite sure that his own horizon bounds the world, he can scarcely expect men who began life by circumnavigating the globe, to agree with his views or to give up their facts in favour of his fallacies.

I feel highly honoured by, though quite unworthy of, the comparison of my views with those of Capt. Maury; and the fact of their accordance, though it subjects both to a common censure by "H. K.," is a source of gratification to myself.

Captain Maury is an officer who has spent a great part of his life in collating and comparing the facts registered by independent observers in all parts of the globe. Naturally, he does not give all the facts, but principally the inferences which he drew from them; but even if the theories he has based on such comparison and collation be not always capable of absolute proof in all cases, yet circumstantial evidence has long been admitted to be of no small value, though a clever lawyer may sometimes have transported or hanged an innocent man by trusting too much to it.

Does "H. K." really suppose that the few facts he has happened to hear or read of, bearing on the argument he has *now* undertaken, of ocean currents, are the sole evidence on the subject? If he will take the trouble to go to the Hydrographic-office, he may find currents, above and below, accurately registered for years past, in all parts of the world; information, comprising pages of observations on the Gibraltar current; volumes of evidence as to deep sea currents in other seas; and, as for surface currents, the strangest thing would be if he did not find a current course in every log—of almost every day—of each ship that ever sailed the ocean. Where, then, has he sought the evidence; on what does he base the assumption that seamen have no power of collecting facts, or assigning to them their just value? What has been his acquaintance with the sea, and its phenomena, that he can afford to treat an Admiral's facts with scorn, and a hydrographer's theories with ridicule? Did he qualify in a Margate hoy? Has he sailed in a Leith smack? Or may we find the place of his nativity in a bathing-box?

It must be—the north has often been the *locale* of such apparitions—he has had a mermaid as a *chere amie*, and she has told him all about it. She was not very well up in physics though, or she would have informed him what was the specific gravity of a barnacle. Perhaps, however, she had one sticking to her tail, and as *it* floated, when *she* floated, why its specific gravity was an idle tale, and not worth taking into consideration. One thing she certainly did not do, and that was to allow him the use of her mirror—

> Oh! wad some fay the giftie gie us,
> To see oursels as ithers see us!

But, as the manner of the times is, "H. K." wants no apprenticeship. At once he proclaims himself master. "Let who will learn—mine it is to teach. At least I can assert, and now-a-days very few will be at the trouble to answer or contradict." Were I disposed to engage in the task of convincing "H. K." of all his errors—for he has "shunted" into currents, and thereby confessed to an unmanageable friction (whether from icebergs or other things) in the cable-laying question—I would without much difficulty show that not one, but hundreds of confirmatory experiments have been made since that trio of facts, which he gratuitously supposes to be the only bases for the opinions held generally by seamen on these subjects. But, first, I may safely leave him in the hands of "An Old Sailor;" and secondly, I can scarcely doubt that the readers of your magazine will be quick to believe a writer, who evinces so little respect for, or knowledge of, the most ordinary physical laws, to be a very untrustworthy guide in the unknown regions of the vast deep—that expanse which, though I have long and widely traversed, I never yet have been through.

Of course, as I said before, if he "kens aught that's no canny," I'll eat humble pie at once, without any compulsion. Commander Dayman would, I am sure, be one of the last officers in the Navy to undervalue the labours of his senior officers, or to call his soundings and ideas the facts, in opposition to which, Captain Maury's, Sir Edward Belcher's, or any other hydrographer's were "groundless suppositions" and "imaginative speculations." I beg to assure "H. K." that when I got soundings, they were certainly not "groundless;" and as I have had the pleasure (?) of arranging some thousands of bits of the bottom, from deep-sea soundings made by Sir Edward Belcher when I was with him, I can testify that his were not so either.

Also that when a seaman is making observations for current, he is not left in doubt whether it be the boat or ship from which he observes, or the current log which he uses, that is in motion. There certainly may be, among persons whom seamen denominate land-lubbers, doubts about seamanship. It is easy to see why. These persons, or some of them, having a high opinion of their own knowledge, make the mistake of thinking that what they do not know, and cannot easily understand, is a myth or a falsity. "I know everything; I don't know this; therefore, there is no such thing—*Q. E. D.*" But I hope there is no great danger of any one in these days mistaking a will-o'-the-wisp for the lime light. So I bid "H. K." adieu; and whenever he leaves his fishy connections and his *incog.*, I shall be happy to introduce him to food for a lifetime in the observation and experiment line.

In the Hydrographic-office these only wait for some English Maury to collate the evidence they afford, and to deduce the valuable inferences which they, and they alone, can furnish. Not till this is done will the general public be aware of what has been done by hydrographers, or of what is, on these subjects, the special knowledge of seamen.

Meanwhile, the public may be assured that such special knowledge does exist, and that whether the problem to be solved be the laws of wave motion or telegraphic submarine communication, from seamen alone—though not from any and every seaman—will they obtain reliable theory or correct information.

Since writing the above, I have seen your last impression; and while I acknowledge the courtesy with which "H. K." thanks "Old Sailor" and myself for the trouble we have jointly and severally taken to refute his reasonings—or rather assumptions—I cannot find any cause to regret that in this letter I have rather used sarcasm than argument.

For when an opponent assumes that to be proved which is not admitted, and proceeds to reason further on such an assumption, a more rational tone is wasted on him, and ridicule is fairly incurred by such an antagonist.

I defy "H. K." to stretch a line over 2,000 miles, or even 500 miles of ocean, without making it bind itself to the bottom of the curvature of the earth—admitting that it were possible (which it is not) so to stretch it at all. If he tried the experiment I recommended with the result to which he alluded, he certainly did so under wrong conditions. Perhaps he strained the line or thread tight—a condition which, as I have said, would be utterly unattainable in practice; or else the thread he used only represented Manilla rope, and was of so light a nature as to float by itself. A telegraph cable, the lightest that would sink at all, or be kept under water between the buoys, would require at least 600 miles of moorings, besides buoys, on the scheme of "H. K."—that is, the buoys, must be not more than six miles apart—three times the depth. Now "Old Sailor" has graphically described a portion of the difficulty of managing these; and I may add that the time consumed in placing each buoy could not be less, and might be much more, than two hours—300 buoys at two hours per buoy = 600 hours. Only 25 days consumed in the operation, or we will say 12½ in each ship, besides the distance to be gone over. Where on earth, sea, or air, does "H. K." think the coals for such work are to come from, or has he a theory that any number of days' coal can be carried in a ship, or that we can coal at sea, in the middle of the at all times delicate operation of cable laying.

As to currents, I recommend now to "H. K." another experiment, which I think will satisfy any one who tries it fairly of the reason why surface currents in one direction should and do generate undercurrents in another and opposite. Let him take a globe of water or aquarium, and having disseminated in it any semi-floating particles in a state of fine division—bread crumbs will do, let him create a surface current by blowing on it, or a more easily visible current by means of a syringe having its nose under water. The flocculi will follow curves, whose tendency will be to increase in size as the operation is continued in one direction till the whole body of water is set in regular motion. The power generated by the mere difference of temperature in the ocean surface, 80 deg. at the Equator and 32 deg. at the Poles, would be sufficient to account for such currents as the Gulf stream, the Arctic current, the Spitzbergen current, and many others well known to seamen, even if the trade winds did not furnish us with another and probable auxiliary in the explanation. Wherever during centuries a force, as wind, has been acting in one direction on water, there will be an eventual forward motion of the whole body, decreasing, it is true, in velocity progressively downwards, but always compensated for by the flowing in of water from a distance; and the operation of the trade winds, the monsoons, &c., are as clearly known to be shown in this way as any physical fact in modern science. With regard to icebergs, I am sure that my friend Sir Edward Belcher would confess that Sir J. Ross's experience on that point is far better than his own. Sir J. Ross says (page 189, answer 3299 of the blue book to which as "H. K." refers), that by the time icebergs get as far south as Cape Farewell they are seldom more than 150 ft. above and 150, fathoms below the surface; and his whole evidence goes to show the great dangers incurred by even laying a cable through such regions, let alone keeping it suspended there. The explanation of the discrepancies between the actual and the calculated immersions referred to by Sir E. Belcher is probably to be found in the fact that such calculations ignore shape. Of course an iceberg in the shape of two cones, with their bases joined at the water-line, might float with six times as much below as above, but another of a more flattened shape generally, yet with a pinnacle of the same apparent height as the one first spoken of, would not float so deeply immersed. But, at any rate, Sir J. Ross did not rely on theory when he saw a whole line of icebergs aground on a bank, the least water on which was 60 fathoms.

I do not by any means admit that wire-rope is more suitable for "H. K.'s" moorings than chain. Rust and barnacles would more speedily destroy it, and it would be less manageable as ground tackle.

I utterly deny that barnacles will not add, and add largely, to the weight the buoys would have to support, or that you could beforehand calculate and provide for such extra weight. The most rudimentary knowledge of the components of shells, barnacle or any other, ought to have convinced "H. K." that this objection is a valid one, and that it does not admit of question, far less of assumption that it is settled. To conclude, it is the fact, that a telegraph cable which passes in one place through a depth of 1,500 fathoms has been for a year, and is now in successful operation. I refer to the Malta and Alexandria line. Had "H. K.'s" theory of superincumbent pressure been capable of accounting for the failure of other lines, no such success could ever exist. The pressure, whether in the test-tank or the ocean, invariably has improved the insulation by the consolidation of the material, and such pressure is rather to be courted than feared. "H. K." supposes that, in the bottle experiment, the water presses through the glass; not a bit of it. The water pressure forces the cork in—fills the bottom with salt water—and very often gives evidence that it has done so by replacing the cork, with the sealed side *down*, in the neck of the bottle. And, if gutta percha or india rubber contained air-cells like wood, they too would be water-logged, as the wood invariably is by the deep sea pressure.

There is no insuperable difficulty in laying or preserving deep sea telegraph cables on the generally tranquil bed of the ocean, if seamen's knowledge be made use of in the operation; and if the solution of maritime problems be left to those whose life has been past in the acquirement of maritime skill, we shall hear no more of the disgraceful failures which have so long checked the progress of international communication, and hindered the development of submarine telegraphic enterprize.

I am, &c.,

J. H. Selwyn.

[We consider that this controversy has occupied sufficient space in our columns, and must decline inserting any more letters on it at present.—Ed. M. M.]

Miscellanea.

A transport vessel on a new plan has just been completed at Cherbourg, France. Thirty-six others are nearly finished on the same plan, and they are to be increased to 50. Each vessel is capable of accommodating 1,000 men, so that in case of necessity the flotilla at Cherbourg might transport an army of 50,000 men.

Dr. Riederhoff, says *Galignani*, has successfully administered fatty substances as an antidote to strychnine. From experiments instituted on about 30 dogs and rabbits, it appears that the absorption of strychnine and its compounds is prevented by administering fat, butter, or oil, the first being more active. Time is thus gained to proceed to other remedies, such as emetics; but as any fatty substance also impedes the action of the latter, they must be given in larger doses, or else the stomach-pump should be used. At all events, fat seems to be more efficacious than other antidotes in the case of poisoning by strychnine, especially more so than morphine, conicine, or aconitine.

The Cambria Iron Company (Pittsburgh, U.S.) have just turned out of their foundry the rim of the fly-wheel for their new rolling mill. It is cast in one piece, and is 20 ft. in diameter, and weighs 23 tons. Larger castings of this character are seldom made. The engine for which this wheel is intended is on the ground, and being rapidly put into place. From the size of the fly-wheel some idea can be formed of the power of the engine.

A New Material for Ceramic Manufactures.—Dr. Muspratt, Principal of the Liverpool College of Chemistry, is of opinion, from an analysis he has made of a sample of phosphate of lime from Estremadura, the almost inexhaustible supplies of which have lately been made available by the concession of the right of working the quarries to Mr. F. K. Dumas, of London, that it is admirably adapted, on account of its purity, for the manufacture of porcelain and Parian. It contains 93 per cent. of phosphate of lime, nearly 4 per cent. of silica, a little phosphate of magnesia, and a trace of carbonate of lime. The phosphate worked at the island of Sambrero, of which Mr. Dumas is the consignee, is of analogous composition to that of Estremadura.

Watchmaking by Machinery in America.—In Waltham, Massachusetts, there is a watch manufactory which employs nearly 500 artizans, and turns out 50,000 watches annually. All the works of the watches are made by machinery. One pound of wire, worth a guinea, is converted into 100,000 watch screws worth £700. The jewels are perforated by a drill which is as fine as a spider's web, and the perforations are measured by gauges that indicate the ten-thousandth part of an inch. If a Waltham watch gets out of order anywhere in America, any part of the works can be obtained, exactly suitable, by sending the number of the watch to the manufactory.

A Novel Launch of a Steamer.—Traction Engine Trail.—A screw steamer which was built at Messrs. Davidson and Wood's yard, North-street, was on Wednesday evening and yesterday morning, conveyed to the river by means of a traction engine. The vessel is 95 ft. long, with 19 ft. breadth of beam, 8½ ft. in depth, 150 tons register, and weighed with the truck on which it was carried about 45 tons. It was brought to the foot of the steep hill in North-street, immediately below St. Vincent-street, by means of blocks and other tackle, by hand labour, during the day. The engine which has just been completed by Messrs. Alexander Chaplin and Co., for Bray's Traction Engine Company, London, possesses the advantages of both Bray's and Chaplin's patented improvements. It has a pair of cylinders seven in. diameter, with three sets of spur gearing (made of Messrs. M'Haffie and Forsyth's improved malleable cast-iron) to the wheels, for speeds of two, four, and eight miles an hour respectively. It arrived at the vessel about half-past eight o'clock on Wednesdey evening, and the tackle being made fast, the vessel was easily drawn up the incline by means of a pair of blocks. The vessel after reaching St. Vincent-street, was then swung round and the engine connected. It towed it along St. Vincent-street to the head of Finnieston-street, where the engine had to be disconnected again to allow the vessel to be brought round the corner. Yesterday morning early the engine again got steam up and was connected, when the vessel was taken down to a large crane at Finnieston Quay and lowered into the water. Her machinery of 25-horse power, will be supplied by Messrs. Smith, Garscube-road. She has been named the "Wingfield," and is intended to ply between Glasgow and the Highlands, *via* the Crinan Canal.—*North British Mail.*

A New Locomotive.—On Monday last, says the *Devizes Gazette*, we had the pleasure of witnessing the trial trip of a new traction engine which has just been turned out of the North Wilts Foundry, and which seems to us to come nearer to what is really wanted than anything we have before seen. This engine, which is simple in construction and moderate in cost, is intended to accomplish two objects. While it will draw heavy loads at a slow pace or lighter ones at the rate of 8 miles an hour, it is applicable to general agricultural purposes. In other words, it will plough and thrash all the week, and bring the corn to market if required, and that at a cost which no horses could ever attempt to compete with. On Monday it started from the Foundry along the London-road, drawing behind it 14 tons, besides its own weight of 8 tons. For instance, it had behind it a portable engine weighing 3 tons, and two carriages weighing half a ton each, containing 10 tons of rough pig iron; and with this weight (of 22 tons altogether) it ran along the road, and up the Bishop's Cannings-hill, which has a gradient averaging 1 in 16, with all the ease imaginable. Indeed, we believe it would have carried half as much again behind it. But what was most observable was the perfect control under which it appeared to be; it was turned round the sharp corner leading into Bishop's Cannings village, and again into the Horton-road, without the slightest difficulty, and was pulled up, at the instant and on the spot, several times during the journey, in order to avoid the chance of accident to the vehicles that were met on the road. The traction engine was made by Brown and May, of Devizes.

The Source of the Nile.—The telegraphic announcement of the discovery of the source of the Nile, made a few days ago, has been followed by the publication of a summarized narrative, prepared from the papers of Captain Speke and Captain Grant. The narrative was laid before the members of the Royal Geographical Society by Sir Roderick Murchison, on Monday, and it embodies a vast amount of interesting information. The explorers are expected to arrive in England during the first week in June, and in the meantime the public will read with pleasure the record of their labours and of their success.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 2907, 2921.
Boilers and Furnaces, 2908. 2925, 2926.
Ships and Boats, including their fittings, 2932, 2940.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 2924, 2944.
Cultivation of the Soil, including agricultural implements and machines, 2920.
Food and Beverages, including apparatus for preparing food for men and animals, 2927.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 2900, 2901, 2914, 2918, 2922, 2928, 2934, 2936.
Buildings and Building Materials, 2933.
Lighting, Heating, and Ventilating, 2905, 2915, 2929, 2938.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 2902, 2911, 2916, 2917, 2923, 2935, 2939, 2941, 2942, 2946.
Metals, including apparatus for their manufacture, 2899, 2903, 2904, 2909, 2913, 2930.
Chemistry and Photography, 2906, 2937.
Electrical Apparatus—*none.*
Warfare, 2910, 2931, 2945.
Letter-Press Printing—*none.*
Miscellaneous, 2912, 2919, 2943.

2899. J. Fletcher and J. Fletcher, jun. *Improvements in machinery for shaping iron and other metals.* Dated October 28, 1862.

This invention relates more particularly, but not exclusively, to machinery for producing the spokes of iron wheels, bolts, and such like articles, having several diameters and variations in section or form, in order that they may be produced uniformly and rapidly from bars of square, hexagonal, octagonal, or other shape. In making bolts, in order to reduce the bar to the required diameter, the inventors pass the bar through rollers having grooves alternately oval and round, so that, after passing through the one, the bar is turned half round and passed through the next. Bolts, with hemispherical heads and partly square body, are rolled from a square bar of the same size as the square part of the bolt, and the head is formed in a heading machine. Bolts, having square, hexagonal, or octagonal heads, and a partly square body, are rolled from square, hexagonal, or octagonal bars, and are first passed through suitable grooves to form the square part of the bolt, and afterwards through an oval and a round groove to form the round part or the part of smallest section. The bar to be treated, say, for the purpose of making bolts, may be of the same form and size as the head of the finished bolt; it is reduced, whilst hot, between rollers having suitable grooves therein, and by means of a reciprocating movement backward and forward, instead of an entire revolution, the point of the bolt is reduced, and the length or extent required between the point and the shoulder is regulated by means of adjustable stops or gauges in each groove within the limits of stroke or partial revolution. For making plain round bolts, with hexagonal or other shaped heads, the larger diameter may be cut by means of a saw sufficiently long to allow for the height or depth of the head; the pieces then may be placed in the dies of a heading machine, where the corners of the head are rounded off and the head squared down, so as to form a shoulder at right angles to the axis of the bolt. The rolls of the machine in which the reduction is effected have part of the circumference of each grooved to the requisite size and form for the smallest part of the bolt, and also with a recess or larger grooving to allow of the introduced part of the bar to go forward up to or beyond the centre line of the rolls without being acted upon. By this means the reduction of diameter is carried up to a square shoulder. The diametrically opposite parts of each of the rolls should be made similar, so that when one part is worn out the rolls may be shifted round and the opposite side used. The pair of rolls are made alike, so that the two small grooves are opposed to each other during the partial rotation. *Patent abandoned.*

2900. E. and A. Tatham. *An improvement in warp machines for the manufacture of looped fabrics.* Dated October 28, 1862.

This invention consists in the employment of metal bars or levers, as described, instead of strings, for dividing and pushing aside the spring guides in warp machines as required according to the pattern to be performed. The levers are free to play upon fixed points, and have motion communicated to them from the jacquard through strings connected to the long arms of the levers. *Patent completed.*

2901. H. Allen. *Improved apparatus for preparing leaves and stalks of plants for being cleaned or dressed for the purpose of obtaining the useful fibres they contain.* Dated October 28, 1862.

This invention relates to mechanism for dividing up in a longitudinal direction, leaves or stalks which have thick butt ends, the object of the invention being to reduce the leaves or stalks to such a state that they may be cleaned or dressed without the risk of the useful fibres they contain being tangled or matted up in the operation. To this end the inventor passes the leaves or stalks longitudinally under the knives or cutting instruments, whereby they are sliced into narrow strips, which may be easily operated upon by the cleaning or dressing machine. The apparatus consists of a table on which the leaves or stalks are placed, and on which they are moved or drawn forwards by two nipping rollers, while a series of knives or cutting instruments secured in a bar are brought down thereon. A convenient mode of working this bar is to mount it on a hinge or centre pin at one end, and connect the other to a treadle lever, whereby it may be brought down when required by the foot of the attendant. The principal feature of novelty in this invention, however, consists in subdividing the leaves or stalks into narrow strips by means of suitable cutting instruments. *Patent abandoned.*

2902. G. H. Smith. *Improvements in the manufacture of crinoline or elastic hoops for dresses.* Dated October 28, 1862.

This invention consists in combining metallic and fibrous strands together for the purpose of forming an elastic fabric suitable for making elastic hoops for dresses. In carrying out this invention, the metallic and fibrous strands are arranged side by side in the form of a warp, and are woven into a fabric of the desired width by the introduction of ordinary weft threads. *Patent abandoned.*

2903. E. S. Tudor. *Improvements in the purification of lead.* Dated October 28, 1862.

This invention consists in subjecting the lead melted in a furnace, pot, crucible, or any other suitable vessel or apparatus, to the action of litharge or other oxide of lead in a state of fusion or semi-fusion. *Patent completed.*

2904. C. S. Duncan. *An improved compound or material for coating or covering metallic and vegetable substances to preserve them from corrosion or decay.* Dated October 28, 1862.

In carrying out this invention, the patentee proposes to use marine glue, gutta percha, india rubber, shellac, copal, mastic, vegetable, or mineral pitch, tar, resin, iodine, sulphur, creosote, or asphalte, bitumen, and coal tar, in combination with one or more of the following substances—alumina, schist, quartz, slate, silex or flint, marble or pozzolano, sand, sandstone, cement (natural or artificial), chalk, glass, emery, tripoli, white oxide of zinc or of lead, or the litharge or red oxide of lead, in every case reduced to a fine and nearly impalpable powder, in proportions varying from one-fourth part to five parts of these powdered materials to one part or more of the before-mentioned plastic substances. The materials are then to be heated, so as to reduce them to a plastic or semi-liquid state, and he also heats the metal or metals to be coated with the compound to a moderate temperature, and while in this heated state he lays on the coating with brushes, or by any convenient method. Immediately after the coating has been laid on the metal, wood, or other body to be preserved, and before it is allowed to cool, the compound is to be covered with a layer of one or more of these mineral powders before-mentioned in a warm state, in order to entirely remove all stickiness or tack. When the compound has become cool, the surface may be brought to a smooth or polished exterior by rubbing it with any ordinary substance used for rubbing down or polishing mineral or metallic surfaces. *Patent completed.*

2905. J. Jeffreys. *Improvements in constructing surface condensers and apparatus for heating and cooling fluids.* Dated October 28, 1862.

In constructing surface condensers of steam engines, the inventor employs thin plates of copper or other metal, which he presses or stamps with numerous parallel flutes, separated the one from the other by flat ridges. These plates are then placed together in pairs, face to face, so that the ridges of one plate come truly over those of the other; but they are separated by a soldering or brazing metal placed between the two. The pairs of fluted plates thus arranged are piled up one pile over the other, but with suitably fluted plates of iron between the pairs, so as to make a solid pile, which is then placed under pressure to bring the ridges of the two plates of each pair close up the one to the other. In this state the pile is heated till the soldering or brazing metal melts, when the pile still under pressure, or placed if necessary under increased pressure in a press, is allowed to cool. In this manner a perfect union of the ridges is obtained, each pair of plates becoming a set of tubes. These sets of tubes may be connected together by turning up the edges of the plates of which they are formed, and enclosing them in a split tube, into which cement or solder is then cast or soldered; or brazed joints may be employed. The whole arrangement is enclosed in a case, and the steam to be condensed is caused to pass into the tubular spaces, whilst the cooling or condensing water is made to circulate in the spaces between the pairs of plates. *Patent abandoned.*

2906. T. Sutton. *Improvements in preparing albumenized paper for photographic purposes.* Dated October 28, 1862.

It is, according to this invention, proposed to prepare the paper before albumenizing it by soaking it in a solution of india rubber, gutta percha, benzole, or any of the other suitable solvents of these substances; for example, chloroform, kerosolene, or bisulphide of carbon. A very good solution for the purpose consists of five grains of india rubber dissolved in one ounce of benzole. After the paper has been immersed in this solution and dried, it is to be albumenized in the usual manner. *Patent completed.*

2907. A. Ripley. *Improvements in the construction of pistons for steam engines, which improvements are also applicable to air and liquid pumps.* Dated October 29, 1862.

This invention consists in certain improvements in the construction of the said pistons, and the object of the invention is the production of a piston which shall permanently possess a self-maintaining steam-tight expanding metal packing, the expansion being constantly maintained by the pressure of the steam, air, or other fluid itself. *Patent completed.*

2908. A. Shanks and F. Kohn. *Improvements in hydrostatic presses.* Dated October 29, 1862.

This invention consists in making a hydrostatic press worked by steam power, in such manner as to exert the direct pressure of the steam upon the water in the main cylinder of the press, by opening a free communication between this cylinder and the boiler, and moving the ram by this direct pressure until the resistance of the object operated upon be equal to this pressure, at which moment steam is admitted under a large piston operating on a ram of smaller diameter in communication with the main arm, so that the motion of the lesser ram produces on the larger one an increased pressure in the ratio of their respective areas. *Patent completed.*

2909. G. Darlington. *Improvements in the manufacture of zinc oxide.* Dated October 29, 1862.

This invention consists in the production of zinc oxide by the use of a smokeless carbonaceous fuel, acting upon a zinc ore in an open furnace, so as to form oxide of zinc, which, passing out of the furnace, is conducted to the collecting apparatus where it is deposited. A coarsely ground mixture of the ores of carbonate or silicate of zinc (with or without flux) and anthracite coal or other smokeless fuel, is placed in a furnace opening into passages leading to a collecting apparatus, and subjected to heat produced by the combustion of similar smokeless coal or fuel. The mixture may be placed in a separate chamber of a furnace, and adequate heat derived from anthracite or other smokeless fuel made to pervade the entire mass; or it may be mixed with such heating material, and in either case the zinc oxide is extracted or separated from the ore and deposited in the collecting apparatus. *Patent completed.*

2910. A. Krupp. *Certain improvements in breech loading firearms.* Dated October 29, 1862.

This invention consists in opening and closing the breech of ordnance and other firearms by means of a sliding valve, or wedge piece, moving at a right angle or other angle to the axis of the bore of the gun. This wedge piece, or sliding valve, works horizontally, and may be provided or combined with various arrangements for the purposes of more effectually preventing the escape of gas at the breech when the piece or arm is discharged, and of simplifying manipulation. *Patent completed.*

2911. A. Hogg. *Improvements in smoothing irons.* Dated October 29, 1862.

In one modification of this invention, the body of the iron is in the form of a hollow box of a square shape in cross section, and pointed at one or both ends. The box is formed with two ironing faces, and the other two sides are perforated or open. Through the centre of the box there is passed a pipe, which is pierced with minute holes for gas jets, and gas being admitted to this central jet pipe by means of a flexible or jointed tube, the jets are ignited, and heat the side of the box which for the time being is uppermost. Openings may be provided to admit air to admix with the gas before ignition, as in what is known as the "Bunsen" burner. When the top side is sufficiently heated for use it is turned down, and the side which was downwards before is in its turn heated by the gas jets in readiness for use by the time the other side becomes cooled. To permit of the iron being turned in this way, it is connected to the handle bow so as to turn about its axis in the bow, whilst a pin inserted through a hole in the bow into either of two holes in the iron or box serves to fit it in either position. The central gas jet pipe is fixed to the bow, so that it keeps its position notwithstanding the turning of the iron or box. One of the perforated sides is made removable, so that the interior may be cleaned. *Patent abandoned.*

2912. W. Clark. *Improvements in apparatus for ascertaining and recording the speed and distance travelled by vehicles, the flow and quantity of water, and other analogous purposes.* (A communication.) Dated October 29, 1862.

The principal features of novelty on which the present invention is based are as follows:—1, A band of paper of suitable width, and of a ctrtain length, without any previous preparation, is wound on a reel or bobbin, and is replaced by another when used up. This paper strip receives the various accidental marks or chronometric points, the nature of which is determined according to that of the operation to be controlled. This band is divided and pointed by the instrument itself, so that the divisions of time shall be indicated by groups and details clearly and visibly, by means of a pointer which cannot err with regard to the fidelity of its indications. 2, Two cylinders are suitably disposed, and carry a band with them in their chronometric motion, which strip is graduated to an extent according to the purpose for which it is required, and divided into fractions of hours, or by measures according to each impulse imparted by means of points projecting on one of the cylinders, and taking into the other one in the manner of toothed gearing. 3. A series of piercers of various forms, indicative of the nature of the operation, are caused to pierce the band at the divisions without arresting its progress at the moment where the controlling action is accomplished: that is to say, at its commencement and termination, according to the order previously determined by the nature of the operation. The parts for actuating the apparatus are appropriate to each kind of operation, and they are both regular and accidental in their action. *Patent completed.*

2913. W. Clark. *Improvements in the treatment of copper ores and in apparatus for the same.* (A communication.) Dated October 29, 1862.

The patentee claims—1, The method of extracting metallic copper direct from any kind of matt, by the simple action of air projected on the matt while at a red heat, or by injecting air into the matt in a state of fusion, and apparatus applied as described. 2, Refining all kinds of copper while in an impure state by the injection of air into the interior of the metallic bath; also by the admission of steam into the said bath, and intimately mixing charcoal or coke in powder therewith. 3, The method of extracting metallic copper from ores containing copper pyrites, and from grey copper ores, by treating the said ores in a blast furnace with carbon, and with the action of air injected as in ordinary blast furnaces, or with steam injected, all as described. *Patent completed.*

2914. J. W. Lister, A. Bottomley, and W. Bottomley. *Improvements in looms for weaving.* Dated October 29, 1862.

This invention relates to the letting-off and taking-up motions. The inventors propose to have for the letting-off motion a warp beam as usual, and instead of applying the friction to the warp beam, they employ three or more rollers, which take the warp from the warp beam, and the friction is applied to one or more of these rollers. The taking-up motion they propose to make as follows:—The cloth comes over the cloth beam in the usual way, when it is taken hold of by three or more rollers (geared and pressed together, and driven from some convenient part of the loom) which take the cloth as it is woven and wind it on the cloth roller. *Patent abandoned.*

2915. W. Cooke. *Improvements in apparatus for ventilating.* Dated October 29, 1862.

One portion of these improvements consists in constructing ventilators formed of wire-gauze or other material, perforated or otherwise, so as to fit any window or such like opening, the same principle being also applicable to window cornices, poles, and the ordinary dwarf wire gauze blinds for the purposes of ventilation or otherwise. Another portion of the improvements relates to the fastening of such ventilators, blinds, cornices, or poles, by means of a fastening attached to the window frame or beading, of a socket or other required shape. Another portion of the invention relates to improvements by which ventilators are constructed of wire gauze, or other perforated material, of two or more folds or slabs at an angle to each other, and which may be made stationary or to expand or contract at pleasure. Another of the improvements consists in the means of elongating the ventilators, window cornices, blinds, or poles by the means of a peculiar arrangement of the ends of such ventilators, by which they may be extended or contracted at pleasure. And another improvement consists in the application of wire gauze, or other perforated material, to the top and the bottom of a window or other such like opening, in such manner that, by the means of a cord or other suitable arrangement, they may be made to act and work simultaneously or otherwise, so as to permit ventilation at both top and bottom of the window or opening to which they are affixed. *Patent abandoned.*

2916. W. E. Evans. *Improvements in apparatus for playing organs, harmoniums, pianos, and other similar keyed instruments and also improvements in reed musical instruments.* Dated October 29, 1862.

In chamber organs, harmoniums, pianos, and similar instruments, it is very inconvenient to arrange pedal keys, as is usual in large organs, in consequence of the space they occupy, and the additional room that is required under the key board to give freedom for the movement of the legs, as is required in pedaling. According to this invention, to obviate these inconveniences, the inventor constructs an apparatus which can be applied to an ordinary chamber organ, harmonium, piano, or other similar keyed instrument, when it is desired to play it by means of pedal keys in conjunction with finger keys. This apparatus consists of finger key board or finger key boards, and pedals underneath, coupled therewith; each finger key is made when depressed to give motion to a lever, the end of which, when the apparatus is in its place for playing the instrument, stands over the corresponding key of the ordinary finger key board of the instrument to be played, so that, when a finger key of the playing apparatus is depressed, the corresponding key of the instrument itself is struck by the lever, and the instrument is caused to sound, the pedal keys (as before mentioned) being coupled with the finger keys thereof act in a similar manner. The playing apparatus, when not required for use, being separate from the instrument, can be moved away therefrom. *Patent abandoned.*

2917. W. E. Gedge. *Improved apparatus in connection with the pans of water-closets.* (A communication.) Dated October 29, 1862.

In carrying out this invention, the inventor proposes to fit on to the shaft of the trap of the pan a crank connected by a rod with a lever, one end of which is furnished with a counter weight to close the trap when the foot is removed from the pedal, and the other covered by a pedal of thin metal screwed to the flooring, in order that it may not catch in or tear the clothes; on this the foot is placed to bring the trap into action. For double-action pans, a cock is seated on the shaft of the trap, so that it and the trap open at the same moment. *Patent abandoned.*

2918. W. E. Gedge. *Improvements in looms for weaving.* (A communication.) Dated October 29, 1862.

This invention consists in a continuous shuttle box and an endless chain with eccentrics. The system of continuous shuttle boxes consists in employing as many shuttles as there are different colours to be used in the manufacture of a fabric, a cylindrical box turning each time that the colour of the shoots must vary, this movement being produced by means of a counter or meter, which is regulated beforehand, according to the pattern of the fabric. The object of the chain with the eccentrics is to make simultaneously all sorts of fabrics as promptly as glossy or glazed stuffs. *Patent completed.*

2919. D. Fryer and J. W. Meears. *Improvements in casks, tanks, or other receptacles for containing petroleum or other oils or spirits.* Dated October 29, 1862.

This invention consists in the application of a moveable lining to the interior of the cask, tank, or other receptacle for containing the above class of liquids, the object being to prevent the contact of the oil or spirit with the cask or receptacle itself, and to obviate the consequent impregation, as well as to prevent loss by leakage. The lining is to be made of vulcanized india rubber. *Patent abandoned.*

2920. J. Head. *Improvements in machinery employed when cultivating land by steam power.* Dated October 29, 1862.

In order that steam cultivation may be continued when too dark to see to steer the cultivating implements, the inventor applies apparatus to the implements and machinery for carrying lamps, and provides for telegraphy by means of lights between the engines, the cultivating implements, and the anchoring apparatus. This he prefers to accomplish by means of four lamps, three of them for signals, and the fourth, a large bull's-eye lamp, concentrating its light in one direction. *Patent abandoned.*

2921. J. Unsworth. *Improvements in steam engines.* Dated October 29, 1862.

This invention relates to certain modifications and combinations of the valves, cylinders, and ports of steam engines, with a view to avoiding compression or back pressure in the main cylinder. For this purpose, according to one arrangement, the pipes or passages employed to convey the steam to two small cylinders alternately are placed close to each end of the main cylinder, and additional ports, which are to prevent back pressure or compression, are placed within about 2¼ in. of each end of this cylinder, so that, when the piston reaches the end of the cylinder, it covers the port which has been opened to prevent back pressure; but so soon as steam is admitted into the large cylinder, it moves the piston valve in the small cylinders, and closes the port upon which the main piston is standing, opening at the same time a port at the opposite end of the main cylinder. This is performed whilst the crank is travelling over the centre. The steam admitted into the small cylinder returns as soon as the exhaust port is opened to the large cylinder. This arrangement prevents any escape of steam. If preferred, the steam may be admitted into the small cylinder or cylinders direct from the boiler. In this arrangement the small cylinders are situate opposite, or nearly opposite, to each other. The entire apparatus is fitted on to a metal plate, the length of which must be in accordance with the engine cylinder upon which it is bolted, the communication from the large cylinder to the small ones being through this plate. *Patent completed.*

2922. F. L. STOTT. *Improvements applicable to mechanism or apparatus for warping yarns or threads.* Dated October 29, 1862.

This invention relates to warping machinery known as warping mills, and to that part termed the "heck," and refers, in the first place, to a modification of the common eye-heck having an eye for each thread, and consists in curving the bars in which the eyes of the heck are secured, and in turning each eye to such a position that the axis of the hole forming the eye will be in a radial line drawn from the centre of the radius to which the heck is curved, so that the line of the axis of each eye will agree as near as practicable with the direction of a horizontal line drawn from the bobbin in the creel or form, a point vertically above or below the bobbin to the eye in the heck. The improvement also consists in curving beer hecks, which are placed between the eye-hecks and the pot-rollers to correspond with the curvature of the eye-heck. *Patent completed.*

2923. A. P. F. NEWHAM. *Improvements in the manufacture or production of reversible shawls.* Dated October 29, 1862.

For the purposes of this invention, the inventor manufactures or produces an improved shawl, in which one, two, or more falls, lappets, turnovers, flaps, or pieces are combined with the body or main piece of the shawl, over each side or surface of which the said falls, lappets, turnovers, or flaps can be turned at pleasure from the top of the shawl, each one as turned over modifying or altering the appearance or design of the shawl, and by having the main piece of the falls, lappets, turnovers, flaps, or pieces presentable on both sides, the appearance or design of the shawl may, by reversing it, be further varied, according to the side presented to view. *Patent abandoned.*

2924. J. FLETCHER and J. FLETCHER, jun. *Improvements in forming wrought-iron wheels, and in the tools for making the same.* Dated October 29, 1862.

In forming wrought-iron wheels according to this invention, the inventors make each spoke-piece of such a length that, by bending it over to form part or portion of the circumference of the wheel frame, and thinning and bending the point over, when the several pieces are assembled, the extreme end of one bent spoke piece is brought in contact with the back of the rounded corner or outside angle of the next bent spoke piece; the curved space left between them is closed or made good by an angular filling piece, the requisite number of which being inserted round the wheel frame, they are then welded up and so make the ring complete. The inner ends of each of these spokes are brought together to form the boss, and wedge pieces are introduced between them. On one face of the wedge piece a groove is formed; there is also a corresponding groove on the inner edge of the spoke, so that, when the pieces are brought together, these grooves form a square or round rivet hole. On each side of the boss a washer is laid, and, having holes corresponding to those made through the boss, rivets are inserted, and the two washers and the boss are securely riveted together, and afterwards welded and forged. *Patent abandoned.*

2925. J. LOCKWOOD. *Improvements in boilers.* Dated October 30, 1862.

This invention consists in placing fire-clay or metal of cylindrical or other suitable form behind the bridge in the flues of Cornish or other boilers, which reduce the area so as to cause the flames to circulate or pass on all sides thereof, and impinge more keenly on the heating surfaces, whereby steam will be generated more rapidly, and fuel economized, and the great heat imparted to the fire-clay or metal will ignite the combustible gases as they pass from the furnace, and thereby prevent or consume the smoke. *Patent abandoned.*

2926. H. EASTWOOD. *Improvements in boilers and furnaces.* Dated October 30, 1862.

This invention consists in constructing tubular boilers with furnaces having hollow grate bars and down draught, and ordinary furnaces underneath, as described. *Patent completed.*

2927. F. GREGORY. *Improvements in presses for pressing seeds, fruits, hops, and other substances.* Dated October 30, 1862.

The cross-head of the press is, according to this invention, supported by two or more columns in the usual manner. Instead of turning the screw for the purpose of moving the ram or platen up and down, the patentee causes the nut to revolve, so that the screw moves up and down without turning. On the nut he fixes or casts a bevel wheel on a driving shaft, and likewise on the nut he fixes or casts a worm wheel, and gears it into an endless screw or worm on another shaft. When the pressure is required, he gives a slow motion to the nut by turning the worm geared into the worm wheel, and when the screw ram or platen are to be moved to or from the material, he puts the worm out of gear with the worm wheel, and causes the nut to be turned more quickly by turning the bevel wheel geared into the bevel wheel at the end of the nut. *Patent completed.*

2928. G. MAYALL and J. HOLLINGSWORTH. *Certain improvements in machinery or apparatus for preparing cotton and other fibrous materials for spinning.* Dated October 30, 1862.

This invention relates to improvements in apparatus for steaming and damping cotton or other fibrous materials whilst being prepared to be spun, such process forming a portion of the said preparation. The apparatus is to be applied to such machines as are employed to open the cotton, and consists in a perforated chamber supplied with steam, and situated or placed beneath the endless travelling cloth or "delivery lattice," which is employed to convey the fibrous material from the machine. The steam ascends from the perforated chamber through the interstices of the lattice, and permeates the fibrous material as required, the diffusion of the steam being prevented by means of a cover above the cotton terminating in a channel or flue to convey the steam away. The amount of saturation is governed by the quantity of steam admitted to the chamber, such supply being regulated by a tap. *Patent completed.*

2929. J. EATON. *An improvement or improvements in the manufacture of certain kinds of gas burners for illuminating purposes.* Dated October 30, 1862.

In making gas burners according to this invention, the inventor bends a piece of iron tubing into the form of a ring, and joins the ends together by brazing. The said ring is supported by the pipe conveying the gas, which pipe is brazed to the ring either at the point where the ends of the tube are joined or at any other part. On the upper side of the tubular ring, holes of the requisite size are drilled for the passage of the gas. The small iron tubing he employs may either be of a cylindrical figure, or flattened. *Patent abandoned.*

2930. G. PIGGOT. *New or improved machinery for punching, shearing, and riveting sheets or plates of iron and other metals and alloys.* Dated October 30, 1862.

This invention consists, under one head, of a punching machine for punching rivet holes, or holes for other purposes, in sheets or plates of iron and other metals or alloys. The said machine punches a plate on its two opposite edges or sides, and afterwards, without refixing the plate, punches the ends or sides of the rails at right angles with those first punched. By means of a differential dividing apparatus, which forms part of the machine, the distance between the holes punched may be varied with great nicety. It also may be made to punch plates with any given camber. The invention consists, secondly, of a shearing machine constructed to shear one side and one end of a metallic plate, either at the same time, or at two separate cuts. The invention consists, thirdly, of a machine for riveting together sheets or plates curved to the segment of a circle, the riveting being so effected that the axis of the said rivets are in the direction of radii to the curve of the jointed plates. The machine is also adapted to rivet plain plates. *Patent completed.*

2931. P. GIFFORD. *Improvements in air guns and leather air arms.* Dated October 30, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2932. J. HORTON. *Improvements in the construction of armour-plated ships and fortifications.* Dated October 30, 1862.

In constructing armour-plated ships according to this invention, the inventor forms the ship with hollow ribs or frames, as has before been proposed in the specification of a patent granted to Alexander Samuelson, and dated February 12, 1862 (No. 373), but in place of applying thereto armour plates having flanges, which are butted together and lodged within the hollow ribs or frames, as is there proposed, the present inventor employs armour plates having no flanges, but which are recessed at their edges. These plates are held in their places by T-pieces, the head of each T-piece lapping over the edges of two adjoining plates, and fitting the recesses so as to make a flush surface, the stems of the T-pieces enter and are secured within the hollow ribs or frames. The ends of the armour plates are arranged so as not to come directly one under the other, but the joints are distributed as uniformly as possible over the whole of the ribs or frames, and the hollow ribs or frames, where they are not required to receive T-pieces, are closed in by the ordinary skin of the vessel under the armour plate. In order to prevent the ends of the armour plates from drawing out from their fastenings, he forms the bottom of the recesses at the ends of the plates with grooves, and he makes the heads of the T-pieces with corresponding projections to lock into these grooves. *Patent abandoned.*

2933. J. BIRCH. *Improved apparatus for unstopping or clearing from obstructions drains, water-closets, stack water, and other pipes.* Dated October 30, 1862.

This invention consists of a series of tools or implements of different kinds, which are capable of being adapted to the end of a jointed or other rod, so that they may be introduced into the pipe or tube for the purpose of removing any obstruction that may be found therein. In order to enable the jointed rod to be passed with facility by any projecting part of the tube, two or more anti-friction rollers are mounted on a swivel cross-head or horizontal swivel pin, so that they may rotate thereon in either direction. *Patent abandoned.*

2934. A. GUILD. *Improved apparatns for preparing and treating the leaves and stalks of fibre-yielding plants, and for cleaning and dressing the same.* Dated October 30, 1862.

The first of these improvements relates to a mode of preparing for the subsequent processes of cleaning or dressing such leaves or stalks as are too large or tough to be advantageously operated upon in the dressing or cleaning machine without some previous preparation. The object of this part of the invention is so to prepare the leaves and stalks that they can be the more readily acted upon by any machine for extracting the useful fibres. The machine whereby this object is effected consists of one or more pairs of rollers, between or under which the stalks or leaves are to be fed, and brought under the operation of an adjustable bar, armed with wedges or knives, whereby the leaves or stalks are split or disintegrated lengthways. This bar, which the patentee calls the "splitter," is capable of being pressed more or less on the leaves or stalks by the foot or hand of the operator. By this arrangement of parts, the operation of the knives or wedges may be modified or stopped at the will of the operator, as immediately pressure is taken off the treadle, whereby the splitter is depressed, the latter will be lifted up by the force of a spring, or by a counterbalance weight. Another form of apparatus, and which is perhaps the more preferable form, consists of one or more rollers with wedge-shaped grooves or corrugations at right angles to their axis, so that, by causing the salient edges of these wedge-shaped corrugations to press on the leaves or stalks which are placed upon a table or travelling apron, the fibres may be separated or forced asunder, thereby splitting up and disintegrating the leaves or stalks, as above-mentioned, into strips of fibres, which may be afterwards cleaned in the machine which forms the second part of the invention. This machine cannot be descriped without reference to the drawings. *Patent completed.*

2935. G. HASELTINE. *Improvements in horse-shoe machines.* (A communication.) Dated October 30, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2936. W. ASTROP. *Improvements in the manufature of paper.* Dated October 31, 1862.

This invention consists in the employment of the fibrous portions of the roots, stems, and stalks of the beet, marigold, wurzell, chicory, and rhubarb plants for the manufacture of pulp for paper and cardboard, either separately or in combination with each other, or in combination with any of the pulps now ordinarily used for these purposes. *Patent abandoned.*

2937. W. R. BOWDITCH. *Improvements in carburetting or napthalizing gas and in the apparatus employed therein.* Dated October 31, 1862.

This invention consists in applying heat to vaporize and keep vaporous the hydro-carbons employed for carburetting or napthalizing gas for illumination, and in passing the gas before it is burnt through or over the heated hydro-carbons; also in the heating the hydro-carbons and keeping the volatile products hot by the gas flame itself, and in an improved apparatus to be used for the above purposes. The apparatus cannot be described without reference to the drawings. *Patent completed.*

2938. H. L. CORLETT. *Improvements in the construction of tuyeres.* Dated October 31, 1862.

This invention relates to an improvement in tuyeres of the kind known as "water tuyeres," for smiths' forge fires, cupolas, furnaces, and all purposes where air is introduced into fire to accelerate combustion, the water being, by means of this invention, forced to circulate in a continuous stream through the tuyere in obedience to the law, causing the heated particles of water to ascend to the surface or summit level of any body of water subjected to the action of heat. The circulation and continuous flow of the water prevents the deposit of any foreign matter in the water spaces of the tuyere, which is thus more effectually preserved from the action of the fire than has hitherto been the case. The tuyere, which may be connected in the ordinary manner with the water supply, is formed with an inner shell, constituting the usual air passage, between which inner shell and the outer shell is an annular water space, which is divided into two or more partitions, placed longitudinally, extending so far as in practice may be found desirable from the back in the direction of the front or nozzle end of the tuyere, a space or opening being left there to make a junction between the chambers formed in the annular water space of the tuyere by means of the partitions already described; or, if preferred, the partitions, or either of them, may be extended to the nozzle or front end of the tuyere; or the opening or passage connecting the lower with the upper chamber or chambers may be placed in any part of the partitions already described. *Patent completed.*

2939. G. DICKINSON and E. COOKE. *Improvements in the construction and ornamentation of metallic bedsteads, couches, and children's cots.* Dated October 31, 1862.

This invention consists—1, in constructing corner joints for metallic bedsteads, couches, and children's cots, in the following manner:—Upon that portion of the pillar at which the corner joint is to be made, the patentees make or fix a ring or annular shoulder, having on its edge a vertical rim extending partly round the said ring or shoulder. Above the said ring or shoulder the pillar is screwed, and a screw nut works on the said screwed part. That part of the joint connected to the sides of the bedstead or other frame consists of a flat bar of iron bent at right angles, the bent part of the bar being curved to a semi-cylindrical figure, so as to fit one half of the rod or pillar. This part of the joint is placed upon the pillar, the curved part being within the vertical rim on the shoulder, and the screw-nut is screwed upon the same part. It is thereby held down within the vertical rim and secured to the pillar. The invention consists—2, in ornamenting metallic bedsteads, couches, and children's cots in the following manner:—They take pieces of glass, either cut or moulded on one or both sides into a series of prisms, the said prisms being either convex or concave. They insert and fix pieces of glass of the kind described in the centre of the foot piece, or on other parts of the bedstead, couch, or cot to be ornamented. The figure of the pieces of glass employed gives great glitter or brilliancy to the bedstead, couch, or cot. *Patent completed.*

2940. D. SPINK. *Improvements in the method of propelling ships and other vessels.* Dated October 31, 1862.

This consists in a method of, and machinery for, propelling ships and other vessels by jets of hot air propelled by steam. *Patent completed.*

2941. A. ANDREWS. *An improved tool for cutting and rasping pegs in boots and shoes.* Dated October 31, 1862.

This tool consists of a flat shank provided at both ends with appliances for acting on the pegs which rise through the sole in boots and shoes. At one end of the shank, the appliance is in the form of a rasp at bottom with a cutting edge at top, so formed with ears or guards that, in using the tool, no cutting in the upper leather or lining can occur. At the opposite end, the appliance is in the form of a hollow figure with a cutting edge; this form of cutter also prevents any cutting of the lining or uppers in the use of the tool. Although the inventor prefers the shank to carry appliances, as above described, yet they may be similar at both ends, or the shank may carry one of the before-named appliances at one end only. *Patent completed.*

2942. C. BATHOE (late GUBBINS). *Improvements in irons for ironing.* Dated October 31, 1862.

The object of this invention is to prevent the possibility of singeing the articles being ironed; and the invention consists in dividing the box which contains the red-hot iron for heating the tool into compartments, the lower of which is to contain water or steam, and that above it the red-hot iron, while another compartment above the red-hot iron compartment may contain water, with a communication leading into the bottom compartment. Or the top compartment may contain the red-hot iron, the main feature in the invention being to prevent contact of the heating iron with the base of the tool which bears directly upon the article being ironed. *Patent completed.*

2943. G. H. MORGAN. *Improved mechanical arrangements for raising and lowering bodies.* Dated October 31, 1862.

This invention consists of a number of ladder frames, each being of less width than the other, so that the same may slide one within the other, each having at the lower part thereof a cross piece with a screw socket for taking the action of an upright screw shaft, to be worked by toothed-wheel gearing and pulley, with driving band and cranked handle, or equivalents for the same, by giving motion to which each ladder frame will successfully be lifted, so as to bring the lower end thereof to the top of the next one in which it slides, when it may be secured in position by means of a spring, catch, bolt, or pin, which will hold the same in its position until the whole series or the desired number of the series are thereby elevated, when, by the bodies to be raised being moved up the steps of the ladder frames, the same will be raised up; or they might be raised by being fixed on the top of the innermost ladder frame. Bodies will of course be lowered by a reverse action. *Patent abandoned.*

2944. H. THOMSON. *Improvements in railway signals.* Dated October 31, 1862.

According to this invention, the inventor proposes to place on the inside of the outer rail, both on the up and down lines, a bar or series of bars of iron, according to the length of bar to be acted upon, and to adjust the level of the bars so that the passage of a train or engine shall depress them by the action of the flanges of the wheels of the engine and carriages. He proposes to connect these bars with levers, rods, brackets, and springs, and with chains or wire ropes, so as to form a communication or connection with a hand signal by day, or with a lamp signal by night. *Patent abandoned.*

2945. M. C. C. SINIBALDI. *Improvements in the manufacture of armour plates for ships, fortifications, and forts, and in the manufacture of plates to be used in the construction and building of ships, and for attaching copper or other like protective metal to the outside of metal plates, for making copper bottoms or bottoms with a similar protection to iron ships, and for other purposes.* Dated October 31, 1862.

This method of constructing armour plates for building ships of war is to combine laminated plates of iron and steel, and also pieces of iron without steel, and steel without iron, perfectly wrought by soldering with copper, brass, or suitable metal, or alloys of metals. The invention cannot be fully described without reference to the drawings. *Patent completed.*

2946. G. SPEIGHT. *An improvement in the manufacture of collars for mens' wear.* Dated October 31, 1862.

For the purposes of this invention, the patentee forms the portion of the collar called the "band" of paper or cardboard, and he forms as a separate piece the portion called the "top" of paper or cardboard also. These two pieces he connects or unites by a "top" or piece of "linen," or other textile fabric, which covers the paper or cardboard "top" on the side which is outermost when the collar is in wear; a part of the said linen or other textile "top" also forms what may be called the joint, bend, or flexible portion between the two paper or cardboard portions (allowing the top to be turned down in turn-down collars, or to be set up in stand-up collars). Or the two paper or cardboard portions of the collar, that is to say, the paper or cardboard band and top, may be in one piece, the paper or cardboard top being covered with a top or piece of linen, or other textile fabric, on the side which is outermost when the collar is in wear. The top is thus formed of two materials, an inside and an outside portion, one of paper or cardboard, and the other of linen or other textile fabric; the latter is pasted or otherwise attached to the band at the nearest margin. He fixes or connects the piece or top of linen or other textile fabric to the paper or cardboard top, and he turns the edges or margins of such piece or top of linen or other textile fabric over the corresponding edges or margins of the paper or cardboard top, whereby a superior edge is obtained. By these means, the portion of the collar which, when in wear, requires, on account of the play of the neck or head, considerable flexibility, so as to yield without breaking (and which portion of the collar, when in wear, is exposed to view), will be of linen or textile fabric. He covers the parts at the ends and middle of the band, in which are the button holes, with tabs, patches, or pieces of linen, or other textile fabric. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated Jan. 21, 1863.

192. H. Caro, chemist, and J. Dale, manufacturing chemist, Manchester. Improvements in obtaining colouring matters, part of which improvements is also applicable to dyeing and printing.

Dated Feb. 19, 1863.

451. R. P. Roberts, Kennington-oval. Improved axle boxes for carriages or vehicles. (A communication.)

Dated March 4, 1863.

603. J. F. Gits, Antwerp, manufacturer. An improved furnace for the revivification of animal charcoal.

Dated March 20, 1863.

751. J. Brigham and R. Bickerton, Berwick-upon-Tweed, implement makers. Improvements in reaping or mowing machines.

Dated March 23, 1863.

787. L. Christofleau, 60, Boulevart de Strasbourg, Paris, blacksmith. Improvements in firearms.

Dated April 14, 1863.

940. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in hardening and colouring gypseous limestone and sand and calcareous stones. (A communication.)

Dated April 16, 1863.

955. J. L. McLay, Liverpool, master mariner. Improvements applicable to mariners' compasses.

957. C. Terrett, Clifton-place, Stapleton-road, Bristol, saddler and harness maker. Improvements in preventing incrustation in steam boilers.

959. W. Oldfield, Noble-street, St. Luke's, writing and dressing-case manufacturer. Improvements in the construction of locks, applicable to despatch and other boxes, writing and dressing-cases, and other similar receptacles.

961. T. A. W. Clarke, Leicester, machine maker. An improved construction of shuttle driver, and apparatus for working the same.

Dated April 17, 1863.

963. R. Knight, Dunkirk, France, engineer. Improvements in treating and preparing iron, copper, and other wires for telegraphic and other uses, for the purpose of preserving them from corrosion or decay.

965. T. Richmond, manufacturer, and T. Richmond and D. Harling, machinists, Burnley, Lancaster. Certain improvements in looms for weaving.

967. R. C. Clapham, Walker, Northumberland, analytical chemist. Treating the waste liquors from bleaching powder stills in order to obtain hydrochloric acid and other products therefrom.

969. W. Massingham, Boston, Lincoln, brewer. Improvements in apptratus for cooling liquids.

971. B. J. Webber, Newton Abbott, Devon, engineer and agricultural implement manufacturer. Improvements in apparatus for separating corn from the ears, and for combing straw.

Dated April 18, 1863.

973. W. S. Macdonald, Manchester, practical chemist. Improvements in apparatus for drying animal, vegetable, and mineral substances.

975. W. B. Burden, Malvern. Improvements in wheels and axles applicable to locomotives, carriages, and paddle wheels.

977. T. Hunt, Banbury, Oxford, brewer. Improved apparatus for obtaining motive power.

Dated April 20, 1863.

979. C. Randolph and J. Elder, Glasgow, engineers. Improvements in surface condensers.

Dated April 21, 1863.

985. A. Ford, Stewart's-buildings, Battersea-fields, gentleman, and R. Rigg, 3, Great Winchester-street, City, gentleman. An improved method of re-forming and re-using old or waste vulcanized india rubber.

987. J. Heap, Ashton-under-Lyne, tool maker. Improvements in adjustable wrenches for nut pipes and pins.

991. J. W. Nottingham, Clayton-place, Kennington-road, artist. Improvements in two-wheeled vehicles.

993. H. Donald, Johnstone, Renfrew, engineer. Improvements in machinery or apparatus for bending or straightening metal plates.

995. W. C. Cambridge, Bristol, agricultural implement manufacturer. Improvements in the construction of harrows.

Dated April 22, 1863.

1001. T. Grace, Bristol, agricultural engineer. Improvements in reaping and mowing machines, part of which improvements is applicable to other useful purposes.

1003. E. J. Jeffs, 1a, St. James's-street, Old Steyne, Brighton, auctioneer and estate agent, and T. Turner, Stanley-bridge-wharf, King's-road, Chelsea, mason and pavior. Improvements in the making and constructing of carriage-ways.

Dated April 23, 1863.

1007. J. W. Proffitt, land agent and surveyor, Park-road, Peckham, Surrey, and W. L. Duncan, gentleman, 218, Pembroke-cottages, Caledonian-road. An improved mode and apparatus for distributing sand or any other suitable substance or substances on the rails of railways and tramways.

1009. R. Richardson, Great George-street, Westminster, civil engineer. Improvements in railway permanent way.

1011. W. Clark, 53, Chancery-lane, engineer. Improvements in the manufacture of tiles, and in apparatus for the same. (A communication.)

1013. P. McGregor, Manchester, machine maker. Improvements in machinery for spinning and doubling.

Dated April 24, 1863.

1015. J. B. Daines, 5, Little Argyle street West, gentleman. Improvements in the preparation of stone, plaster, compo, iron, wood, and such like substances, so as to preserve them from decay.

1017. J. Lambert, Sheffield, brass founder. Improvements in ball cocks.

1023. J. Thompson, Bilston, Stafford, manufacturer. Improvements in the manufacture of barrels for firearms and other descriptions of tubes, and in apparatus or machinery to be employed for that purpose.

1025. W. A. Shaw, New York, United States. A mode of lining lead pipe with tin or its alloys.

Dated April 25, 1863.

1029. L. De Breanski, Greenwich. Improved apparatus for fixing drills, which invention is also applicable for fixing apparatus for raising, supporting, and suspending weights, and for other analogous purposes.

1031. A. H. Clark and H. Hope, Birmingham, manufacturers. Improvements in valves for water, steam, and gas.

1033. J. P. and E. B. Nunn, Royston, Cambridge, farmers. Improvements in hoes and cultivators.

1037. F. Walton, British Grove Works, Chiswick. Improvements in the manufacture of fabrics for covering floors and other surfaces, and in the apparatus employed therein.

1039. I. Dimock, machinist, Manchester. Improvements in machinery for cleaning, sorting according to size, and doubling silk and other threads.

1043. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improvements in breech-loading firearms. (A communication.)

Dated April 27, 1863.

1045. S. Osborne, Bayswater, stay and crinoline skirt manufacturer. An improved machine for unwinding crinoline steel.

1047. H. E. Carchon, feather dealer, and E. F. Raybaud, hat and bonnet maker, 17, Rue Thévenot, Paris. Improvements in the manufacture of hats and bonnets, and mode of preparing feathers to be used in the said manufacture.

1049. W. E. Gedge, 11, Wellington street, Strand. Improvements in tuyeres or blast pipes, and in apparatus connected therewith. (A communication.)

1051. W. Richards, Birmingham. Improvements in ordnance, firearms, and cartridges.

1053. F. Bennett, Holywell, Flint, metallurgist. An improved method of condensing lead and other metallic fumes and vapours from furnaces.

1055. W. H. James, Old Kent road, civil engineer. Improvements in indicating the locality of fire, applicable also to denoting the position of ships.

Dated April 28, 1863.

1059. S. Ingledew, Stockton-on-Tees, wharfinger. Certain improvements in the method of obtaining iron from its ore, and in the subsequent treatment thereof for converting the product into a metallic state, and in apparatus connected therewith.

1061. S. Crabtree, Bradford, manager. Improvements in balling motions.

1063. A. Kinder, 20, Cannon street, engineer. Improvements in the manufacture of sheet metal, and in ingots or plates of metal, and in the machinery or apparatus employed therein.

1069. T. Moore, 27, Leadenhall street. Improved apparatus for laying down, protecting, and controlling submarine cables for telegraphing from vessels moored off a coast to the shore.

1071. G. Davies, 1, Serle street, Lincoln's inn, civil engineer. An improved machine for agitating and mixing substances. (A communication.)

1073. H. Y. D. Scott, Brompton Barracks, near Chatham, Capt. R.E. Improvements in the manufacture of cementitious substances.

Dated April 29, 1863.

1075. J. Rowley, Stafford street, Peckham. Improvements in the means or apparatus employed for recovering the fibres of wool from fabrics or materials composed of wool combined with cotton or other vegetable substances.

1077. W. Tarr, 112, York street, Oxford street, Manchester, and E. Tarr, 40, Cavendish street, Oxford street, Manchester. An improvement in pianofortes.

1079. E. and F. A. Leigh, Manchester, mechanical engineers. Improvements in cotton gins and in the method of driving the same, part of which improvements is applicable to other purposes.

1081. H. Worms, 27, Park crescent, Portland place. Improvements in apparatus for elevating guns.

1083. F. Gretton, Burton-upon-Trent, brewer. Improvements in heating the contents of mash tuns.

1085. H. W. Ripley, Montpellier lawn, Cheltenham. Improvements in apparatus for printing fibrous materials. (A communication.)

Dated April 30, 1863.

1087. J. Wibberley, Manchester, mechanic. Improvements in machinery or apparatus for winding cotton, silk, wool, or other threads on spools or reels.

1089. W. Clark, 53, Chancery lane, engineer. Improvements in the manufacture of hydrocyanite of ammonia and of alkaline and earthy cyanides. (A communication.)

1091. E. G. Brewer, 89, Chancery lane, engineer. Improvements in welding and rolling metals, and in machinery connected therewith. (A communication.)

1093. J. Appleby, Manchester, tea merchant. Improvements in propelling ships and barges.

Dated May 1, 1863.

1095. J. McFarlane Gray, 80, Prince Edward street, Liverpool, engineer. Portable apparatus or instruments for riveting, caulking, chipping, and otherwise operating upon and treating metals and other substances.

1096. E. Jones, Charlton. Improvements in drainage and in water-closets, and in the means and apparatus necessary for the same respectively.

1097. W. Clissold, Dudbridge, engineer. Improved apparatus for fulling woollen cloths and washing and cleansing woven fabrics.

1099. J. Badart, 9, Bishopsgate street. Improvements in the preparation of rape seed cake, linseed cake, poppy seed cake, niger seed cake, sesseme seed cake, and ground nut cake.

Dated May 2, 1863.

1101. W. T. Smith, Dalston, engineer. Improvements in washing machines.

1103. G. Burt, Birmingham, manufacturer. Improvements in machinery for punching, stamping, or forging metals.

1105. S. J. Bartlett, Maidstone, watch and clock maker. Improvements in apparatus for straining and drawing off liquids.

1107. J. T. and T. Oakley, Grange-road, Bermondsey, engineers and millwrights. Improvements in the construction of garden pumps, part of which said improvements is applicable to fire-engines and other hydraulic machines.

Dated May 4, 1863.

1109. E. R. Southby, Wareham, Dorset. Improvements in the extraction of scents from plants, flowers, and other odoriferous substances.

1110. J. Fortune, Morton, near Bingley, York. Improved means of joining or fastening together lace, blond, quilling, or similar materials.

1111. J. M., E. J., and C. Johnson, Castle street, Holborn, show tablet manufacturers and printers, and L. Bertling, Ironmonger street, St. Luke's, draughtsman. Improvements in the production of show tablets, advertisement tablets, name plates, architectural facings and decorations, and other ornamental, decorative, and inscriptive articles.

1113. G. Haseltine, 12, Southampton buildings, Chancery lane. Improvements in springs for railway carriages and other purposes. (A communication.)

Dated May 5, 1863.

1115. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in the manufacture of wrought iron and steel, and in the apparatus to be employed therein. (A communication.)

1116. W. Walsh, Manchester, manufacturing chemist, Improvements in obtaining and purifying oxalate of soda, which improvements are also applicable to the manufacture of oxalic acid.

1117. R. G. Kent, Old Compton street, Soho, tool and metal warehouseman. Improvements in the construction and arrangement of shades and reflectors for gas lights.

1119. W. Boothroyd, Halifax, bobbin manufacturer. Improvements in stationary engines or apparatus for obtaining motive power.

1123. J. H. Knott, Nelson square, Blackfriars road, engineer. Improvements in pumps.

1125. W. C. Wilkins, Long Acre, lighthouse engineer. Improvements in lamps.

Dated May 6, 1863.

1127. T. Sagar, Burnley, machine maker, and J. Wilkinson, foreman. Certain improvements in power looms for weaving.

1129. W. E. Gedge, 11, Wellington street, Strand. An improved toy. (A communication.)

1131. S. D. MacKellen, Manchester, watch manufacturer. Certain improvements in watches and other timekeepers.

1132. I. M. Singer, Glasgow, gentleman. Improvements in sewing machines.

1133. G. Davies, 1, Serle street, Lincoln's-inn, civil engineer. Improvements in machinery or apparatus for forging and dressing horse-shoe and other nails. (A communication.)

1135. A. Sturrock, Doncaster, engineer. Improvements in locomotive engines and tenders.

Dated May 7, 1863.

1148. T. Holliday, Huddersfield, manufacturing chemist. An improved blue colouring matter.

1150. A. Skwarcow, 24, Leadenhall-street, merchant. Improvements in the construction of turntables. (A communication.)

1152. J. S. Grimshaw, Huncoat, near Accrington, spinner and manufacturer. Improvements in looms for weaving.

1156. W. Clark, 53, Chancery-lane, engineer. Improvements in coating wrought or other iron to protect it from corrosion or oxydation. (A communication.)

Dated May 9, 1863.

1162. S. Wilson, Manchester, engineer. Improvements in hoops or bands for fastening bales, and in machinery or apparatus for making the same.

1164. J. Norie, Glasgow, ironfounder. Improvements in making moulds for casting, and in apparatus therefor.

1170. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in the manufacture of lamp black. (A communication.)

1172. J. Burrell, 85, Back Church-lane, Whitechapel. Improvements in machinery for cutting the teeth of bevelled wheels.

1174. J. Burrell, 85, Back Church-lane, Whitechapel. Improvements in salinometers.

Dated May 11, 1863.

1178. R. Burgess, Manchester, engraver. Improvements in machinery or apparatus for marking, etching, or engraving cylindrical and other surfaces.

1182. J. Parkinson, Titchbourne-street, Regent-street. A new or improved mode of manufacturing tablets to be used for monumental purposes.

Dated May 12, 1863.

1188. W. Mattison and G. Barker, Leeming-bar, near Bedale, York, iron founders. Improvements in grass mowing and reaping machines.

1194. H. L. Emery, Sloane-street, Chelsea. Improvements in apparatus for manufacturing saws suitable for ginning cotton and for other uses. (A communication.)

1196. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in spring mattresses, sofas, chairs, seats, and similar articles. (A communication.)

Dated May 13, 1863.

1198. H. Rushton, 48a, Northampton-road, Clerkenwell. Improvements in head-dresses.

1202. F. Holthausen, 40, Rue de Richelieu, Paris, manufacturer. An improved portable copying press.

1204. V. J. Cassaignes, 8, Rue des Fosses, St. Jacques, Paris. Improvements in stereoscopes.

1206. B. Lambert, 35, Lothian-road, Camberwell New-road. Improvements in paper-makers' rag or pulp engines.

Dated May 14, 1863.

1210. T. Lawrence, Salford, Lancaster, mechanic. Certain improvements in machinery or apparatus used in the processes or operations of drying, dressing, brushing, waxing, and finishing fabrics.

1212. A. Pilbeam, Glasgow, gentleman. Improvements in sewing machines.

1214. J. Burrell, 85, Back Church-lane, Whitechapel. Improvements in the construction of cocks or valves.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated May 14, 1863.

1218. G. T. Bousfield, Loughborough Park, Brixton. Improvements in machinery for rolling, grinding, and cutting files and rasps. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, May 26, 1863.

105. J. T. Stroud. Fixed and portable lights for domestic and other uses.

106. C. H. Townsend and J. Young. Compositions for preventing incrustation and corrosion in steam boilers and condensers.

129. E. Howes. Railway, ship, and other lamps.

134. R. Ferrier. Wet gas meters.

135. L. P. Josse. Apparatus for cleansing wheat or other grain or seeds.

137. J. P. Bath. Omnibuses.

141. W. E. Newton. Microscopes. (A communication.)

150. J. Edwards. Manufacture of buttons.

156. W. E. Newton. Manufacture of buttons. (A communication.)

164. J. J. Lundy. Manufacture of metallic casks and vessels.

171. H. A. Bonneville. Colouring, bronzing, and preserving iron and steel. (A communication.)

187. E. Bazin. An improved log.

192. H. Caro and J. Dale. Obtaining colouring matters.

193. H. Holcroft. Machinery for separating substances of different specific gravities.

198. J. M. Binger. Paste or composition to cover the rollers used by letter-press printers.

203. T. Lambert. Apparatus for drawing off water or other fluids.

223. R. A. Brooman. Manufacture of anvils. (A communication.)

243. H. B. Barlow. Preserving timber. (A communication.)

252. F. W. Wymer. Steam engines.

259. E. G. Muntz. Securing axles and axle boxes.

271. C. H. G. Williams. Manufacture of red colouring matters.

274. W. Clark. Condensation of steam. (A communication.)

374. R. Saunders. Pavements and floors.

423. S. W. Clough. Signalling on railways.

424. W. Nalder. Rotary screens.

475. E. T. Hughes. Treatment of colouring matters derived from tar for the purpose of making them applicable for painting. (A communication.)

558. W. Gray. Manufacture of beaters for thrashing machines.

593. J. Henderson. Carpets.

913. H. W. Ripley. Preparing and printing wool and other fibres. (A communication.)

1007. J. W. Proffitt and W. L. Duncan. Distributing sand, or any other suitable substance or substances, on the rails of railways and tramways.

1025. W. A. Shaw. Lining lead pipe with tin or its alloys.

1029. L. de Bréanski. Fixing drills; also applicable for fixing apparatus for raising, supporting, and suspending weights.

1048. J. J. Robert. Spoons and forks.

1111. J. M., E., and C. Johnson and L. Bertling. Show tablets, advertisement tablets, name plates, &c.

1132. I. M. Singer. Sewing machines.

1140. P. Bourne, Miners' lamps.

1218. G. T. Bousfield. Rolling, grinding, and cutting files and rasps. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed May 22, 1863.

3167. T. M. Elton.
3170. J. Steinthal.
3171. F. Palling.
3174. J. R. Danks, B. P. and R. P. Walker.
3176. J. Halford.
3179. T. Keyworth.
3180. W. T. Rowlett.
3181. D. Auld and D. Auld, jun.
3183. D. Veerkamp and C. F. A. V. Trigt.
3415. G. E. M. Gérard.
3422. F. Parker.
3473. H. A. Bonneville.

The *Daily News*, July 1st, speaking of Benson's Watches in the Exhibition, says:—"Here are arranged a fine selection of watches manufactured by him on the latest and most approved principles of horological science. When we compare them with the specimens of ancient watch-work which are placed beside them, or even with those worn by our grandfathers, the immense advance in this branch of the mechanical arts is at once apparent." Chronometer, duplex, lever, horizontal, repeaters, centre seconds, keyless, split seconds, and every description of watch, from the plainest to the highest quality of which the art is at present capable, and adapted to all climates. Benson's Illustrated Pamphlet on Clocks and Watches (free by post for two stamps) contains a short history of watch-making, with descriptions and prices. It acts as a guide in the purchase of a clock or watch, and enables those who live in Scotland, Ireland, Wales, the Colonies, India, or any part of the world, to select a clock. J. W. Benson, Prize Medallist, 33 and 34, Ludgate-hill, London.—Established 1749.—[Advertisement.]

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JUNE 5, 1863.

THE BRIGHTON RAILWAY ACCIDENT.

Again our daily journals have had the sad task of recording one of those catastrophes which all our engineering science and mechanical skill seem powerless to prevent. Our readers are by this time too well acquainted with the details of an event which has spread universal consternation, to need further description at our hands.

In the present stage of the inquiry now pending, it is a matter of no little difficulty to determine the immediate cause of the accident. Its ultimate cause is doubtless to be found in the excessive speed, deemed necessary to make up for time previously lost, from causes which we are not just yet in a position to state. Those journals which ought to possess the most accurate information, express curiosity and consternation; wrath towards railway officials, railway directors, railway engine-drivers; all, in short, directly or indirectly connected with an event productive of such lamentable results. But as yet we have none of those details scientifically accurate, because drawn from proper sources, which can alone enable us to pronounce a positive opinion. On one side, we hear the surmise that the engine exploded from the over-pressure required to obtain an excessive speed; from another source, we learn that the engine left the rails first, and exploded afterwards—doubtless, the most correct conclusion. Locomotive engines, indeed, seldom explode when running, with such fatal results. Many instances might be adduced where they have exploded without leaving the rails or doing much damage. It is not quite the easy matter some may imagine, to raise steam to 300 lb. on the square inch, even with a locked safety valve, when an engine is running, as this one is said to have been, at 60 miles an hour. We say 300 lb. solely on the supposition that the engine was in fair working order; of course a channelled or corroded boiler might reduce the limit of strength to a mere trifle over that at which the engine daily worked; but we have no evidence whatever to say that such was the case with the engine in question; nor is it likely that the driver permitted his water to become so short, that overheating the fire-box led to its collapse.

The far more likely conclusion is, that the engine, travelling at an excessive speed round a sharp curve, oscillated so violently as to force out a badly secured rail; and on leaving the track, and falling down the embankment, had some part of the broken machinery forced through the shell of the boiler, when an explosion would be likely enough to follow. The breakage of a connecting rod in inside cylinder engines often enough leads to disastrous results from the forcible entrance of the broken rod into the fire-box shell.

That the oscillation was violent, long continued, and a subject of remark for some time before the occurrence of the accident, is one of the very few facts on which we can with certainty rely. It is just barely within the bounds of possibility that this oscillation might be the indirect cause of an explosion by tearing away some of the plates which attached the boiler to the frame, or the machinery to the boiler. We have before now seen a "motion plate," riveted both to the frame and the barrel of a boiler, completely torn away from the last by the united effects of expansion, and journeys over rough roads, at high speed. In such cases rivet-heads start off, bottom-plates spring, and become so deeply channelled as to render their renewal a matter of necessity. Although it is improbable, it is possible that violent straining on an old and weakened plate might have caused this explosion before the engine left the rails.

The *Times*, in a leader, attributes the accident, or, as it terms it, the "unusual effort," to the fact of the train being 20 minutes late when leaving Croydon. We confess the deduction is too far-fetched for our understanding. Had the article, however, been more grammatical, we might have understood it better. But without, like the *Times*, implying that unpunctuality is a force which can cause a train to leave the rails, we can easily draw the conclusion that the want of punctuality is the most prolific source of railway accidents. Novices in such matters imagine that, the whole system of railway traffic being one of the most complicated under the sun, the slightest departure from the exact times laid down for the setting out and arrival of trains must lead to the disorganization of the whole system. Such does not seem to be the case, however. Our great companies might adopt the mottos, "Time was made for slaves;" they prove themselves free by utterly disregarding it. In such accidents as the present, we see the result.

Whether the intervention of Government would or would not lead to good results, is a question open to discussion. Hitherto, drawing the natural conclusion that the enormous damages should be sufficient penalty on railway companies when accidents could be traced to their negligence, it has not interfered. The deduction would be correct did directors pay for such accidents out of their own pockets; but such is not the case; shareholders, who are blameless, pay; directors escape comparatively untouched. There is such a thing as carrying forbearance too far; and although public companies are too apt to consider the interference of Government officials as a piece of impertinence strongly to be strongly condemned, we think it high time that railway officials should be compelled to keep the time, and observe the bye-laws which experience prove to be necessary to the safety of the passangers who entrust their lives and property to their care; and although we cannot recommend the introduction of a law which would limit speed, we will hail, as a great step in the right direction, such a rigid supervision by proper officials as will ensure the punctual despatch of trains at the hours named by traffic superintendents.

LIGHT LOCOMOTIVES.

Whether much of the odium into which branch lines have fallen with existing railway companies does or does not depend on the mode in which they are worked, is a question which we believe requires little discussion. The defects of existing arrangements by which a 30-ton engine and tender are employed to draw 10 or 15 tons of carriages, and 3 or 4 tons of passengers, ought by this time to have become sufficiently obvious to lead to the adoption of some more economical mode of propulsion. Boards of directors are, however, but fallible, like other men, and too often prefer to adhere, limpet-like, to the dead weight which may almost crush them out of existence, rather than resort to any scheme, no matter how full of promise, to which the hateful word "novel" can be applied.

That the prophecies spoken at the beginning of the railway mania, which foretold a time when every hamlet, if not every farmstead, should have a branch line of its own, will ever be fulfilled, is far more than doubtful. There is certainly no want for such a refinement of intercommunication; a moderate approach to it would, perhaps, lead to the immediate bankruptcy of every railway company in England. Nevertheless, our railway system, extended as it is, hardly yet fulfils all the requirements in its power. Hundreds of towns, towns of 4,000 or 5,000 inhabitants, are still many miles from a railway station—miles sufficient to prevent the railway proving anything like a boon to their commerce or trade. The transport of goods or passengers over a very few miles of turnpike road usually costs quite as much as their conveyance ten times as far by rail. Whole districts, indeed, yet exist which know the benefits of railway communication only by hearsay; and for anything we can see to the contrary, never are likely to experience them practically. Until branch lines pay dividends, their extension is more than problematical.

It is hopeless to expect a fair profit from a few miles of railway with an extremely light traffic, unless its working expenses are light in proportion. The maintenance of the permanent way is always the most serious item in railway disbursements, and it is reasonable enough to expect that on such a line this item should be reduced to the very lowest limit. Were this the case, all would be well; and branch lines being generally found to pay pretty fairly, both directly, and as feeders to the main line, would enjoy a goodly proportion of public favour. But, on the contrary, the half-yearly accounts nearly always show the expenses for maintenance and fuel to be nearly as much per mile as on the main line, with abundantly more traffic. A result sufficiently natural, when we consider that the same class of locomotives work on each.

A branch line having obtained the sanction of Parliament, is constructed at a moderate price, and seems likely to command a fair share of traffic. The permanent way, in order to reduce constructive expenses, is, or at least ought to be, light. The next consideration is the locomotive stock to work it, and this is quickly supplied by some half-dozen engines, considered too antiquated to work the main line traffic. Then we see a 30-ton engine and tender—an old coupled "goods," as often as not—drawing two railway carriages, or perhaps three, weighing about five tons each, and carrying some fifty or sixty passengers. An elephant drawing a Queen's pattern phaeton would not be a whit more ridiculous. The relative weights, indeed, of the propelling powers and the loads drawn, would bear almost exactly the same proportion to each other in each case. The result is apparent enough: at the end of six months the expenses are found enormous, the profits infinitesimal. Nothing remains but to remove the permanent way, if light, and replace it by degrees, at an immense expenditure, by 80 lb. rails, with chairs, &c., in proportion. We do not wonder that shareholders grumble, and directors forswear branch lines for the future.

No policy can be more suicidal, than the practice of an economy which judges it better to work lines of light traffic with heavy engines, simply because they already exist, rather than build or purchase others really suited to the object in view. Such a system of working goes far to prove that both directors and engineers have yet to learn that the actual cause of destruction to the permanent way is to be found in the heavy locomotive, not in the load it draws. Were it but possible to do without locomotives, what an Eldorado would be opened for shareholders! Permanent way would then indeed deserve the title. It could no longer be applied in derision, as it too often is now. But locomotives being necessary evils, the only resource left is to guard as much as possible against the destructive effect due to their weight, by reducing that weight to the lowest limit compatible with the possession of a sufficient amount of adhesion to enable them to perform the duty assigned them. It may often answer to put down a larger engine to drive a factory, or pump a mine, than that actually required at the moment, because many circumstances might arise which would throw an increased demand on the capabilities of the engine. For such contingencies, of course it is well to be prepared; but no argument of this kind can be used in favour of the adoption of heavy locomotives to work light traffic. When that traffic increases, it is easy to replace existing engines with others, heavier and better suited to the increased demand on their powers, while the light machines thus superseded may still do good service on new branches, or other parts of the line where the traffic continues small. After all, we very seldom find such locomotives displaced by their heavier brethren. Strange as it may seem, all experience goes to show that, the smaller the engine, the greater is its proportionate efficiency compared with the dead weight put in motion; indeed, in no case where 10 and 15-ton engines have been employed to perform a duty suited to their powers, have they failed to give the most perfect satisfaction. A consumption of fuel reduced from 22 lb. to 12½ lb. per mile, while transporting the same loads; a 40 lb. or 50 lb. rail outlasting one of 75 lb. or 80 lb.; a proportionate reduction in rolling stock repairs (for a rail cannot be worn out without considerable injury to the wheels and carriages performing the feat); such results soon increase dividends, and lines whose working has been considered almost disastrous begin to pay a fair percentage.

We feel little doubt that light railway carriages, having the locomotive machinery fitted up in one end, on principles long since ably advocated by Mr. Adams and others, would, *cæteris paribus*, supply us with the nearest approach to the theoretical perfection of passenger transport. A pair of 7-inch cylinders, with a 12 in. stroke, in conjunction with suitable boiler and machinery, need not weigh more than 2½ tons, independent of the weight of the framing, which would, of course, be that of the carriage. A large composite carriage thus arranged, and calculated to carry 80 or 90 passengers, should not weigh more than 15 tons. The consumption of fuel would be far below 10 lb. per mile. At least 40 tons of rolling stock are usually put in motion to convey the same number of passengers, with a consumption of some 18 lb. or 20 lb. of fuel for precisely the same duty, on the ordinary system.

But the capabilities of these locomotive carriages do not by any means terminate with their own propulsion. Adhesion is the real measure of the tractive force of every description of locomotive, whether an independent machine or carrying passengers on the same frame. And 8 tons on the driving wheels will supply adhesion enough for a load of 60 tons on steep grades, so that no difficulty stands in the way of coupling two or more additional carriages on when the necessities of the traffic demand increased accommodation. The moderate amount of goods and cattle traffic, which we find on branch lines, could thus easily be carried on without taxing the powers of one of these locomotive carriages to any extent; indeed they have on more than one occasion, under exceptional circumstances, taken their place in main line traffic, and done exceedingly good service while so employed.

Whether the universal adoption of such carriages of a larger and more powerful class, suited to really heavy work, would or would not prove advantageous, must of course remain a disputed question. On our part, we feel no hesitation in saying that such carriages would introduce an element of economy which railway companies would find a positive boon. The hauling about of many tons of dead weight, merely to secure adhesion, cannot be regarded as wise policy. Why not, then, make the increased load aid in supplying the necessary adhesion? A ton of passengers will prove just as effectual in preventing a driving-wheel slipping, as a ton of iron. The transport of the one pays well; the transport of the other is a serious item of expense. Every ton of dead weight we work into a locomotive, may be said to require an additional 5 cwt. to secure the adhesion needful for its own propulsion. The actual cost of conveying passengers is a very small item of expense; trains cost much the same per mile, loaded or empty, simply because the paying load bears so small a proportion to that which does not pay. Where the load is heavy and certain, as on the largest of our main lines, or with a steady mineral traffic, heavy locomotives have been hitherto found indispensable, and have generally paid their way pretty fairly; but, after all, such cases do not really represent more than 60 or 70 per cent. of the entire railway traffic of Great Britain, and there is no reason whatever that the remaining 30 or 40 per cent. should be worked at a loss on the same principle, and by the same engines.

It has been urged that heavy engines are necessary for high speeds, as light locomotives fail to keep time. If coupled to a train whose weight exceeds their powers, this result is likely enough to ensue; but the case would be very different were the 150 or 200 passengers placed in a light locomotive carriage, with high drivers, and of considerable length. We believe that no difficulty would be found in conveying the same paying load, at the pace of our fastest express trains, at much less than one-half the cost, and perhaps with far more safety. The curse of our railway system is that every part almost of our rolling stock is made too heavy; the result is not safety, but destruction and waste. Were it not for the excessive weights placed on our engine tyres to obtain the adhesion necessary to draw, not alone 5 or 10 tons of passengers, but 40 to 100 tons of rolling stock, they would seldom fail; permanent way would seldom be out of order, and accidents far more rare than now.

We cannot, in the space of a short article, enter as fully as we could wish into this important subject; at a future day we may resume it. The whole question of railway economy pivots on the reduction of transported weight to the lowest limit; and the more general introduction of light locomotives should be regarded as an important step in any future attempts at economy.

NOTES OF THE BIRMINGHAM MANUFACTURES.

WE find few engineering establishments in Birmingham which present any features of importance. The manufacture of small goods in iron, brass, or steel may be regarded as its distinguishing characteristic, to the almost total exclusion of the Cyclopean works for which other centres of industry are celebrated. But although within the actual precincts of the town it may be difficult to find an establishment where the construction of heavy machinery is carried on, on a scale large enough to secure the adoption of such mechanical expedients as can alone enable the engineer to conduct his business with profit, a few short trips by rail will bring us to establishments which well repay the trouble. Not the least celebrated in England is the factory where Messrs. Boulton and Watt carry on business at Soho; with little more than a glance at which we must for the present rest content.

We have already stated that it is far from our intention to give detailed descriptions of processes, tools, or machinery with which it is but natural to suppose our readers are perfectly familiar; it is rather our purpose to pick out, as far as possible, such information as is not generally known, and therefore likely to prove interesting.

The present factory is not the original cradle of the steam-engine, in a very accurate sense of the phrase; for that part of the works in which Watt's first engines were built, and most of his experiments conducted, has, we regret to say, been pulled down by the present Mr. Boulton, for reasons which we are not prepared to state. It was situated at a moderate distance from the present factory, which, though in part new, still comprises within its limits many of the old shops in which Watt's ideas were practically developed. Situated within a hundred yards or so of the Soho Railway Station, on the London and North Western, a siding permits the heaviest castings to be loaded directly on the railway waggons in the yard; the canal washes its walls; land is comparatively cheap—a combination of advantages which such establishments seldom possess in the same degree.

On entering the erecting shop, one is struck with its noble proportions, the more remarkable as it is an old part of the factory. One point is worthy of attention—we have never seen a shop of the kind so free from the encumbrances of machine tools; a result due to the judgment observed in placing the planing machines, &c., in situations where they are completely out of the way. The arrangement of some of the planing machines is particularly worthy of attention. Large cylinders, instead of being placed on the moveable tables, and traversed under fixed rests to get up the valve faces, as we find too much the custom, are arranged in a vertical position close to the walls, on suitable beds, to which they are firmly attached; while the tool, fixed in a proper head-stock, which traverses in a vertical frame bolted to the wall, performs its work with the utmost precision. It is, in fact, a vertical planing machine, with a moveable instead of a fixed tool. In another part of the shop is a machine, called a "devil" by the men. It is used chiefly for facing up the flanges of cast-iron pipes, which it does, with sufficient accuracy for all practical purposes. It consists simply of a large face-plate, similar to that of a lathe, the axis on which it is mounted revolving in an ordinary head-stock. Just in front, and nearly on a level with the ground, is a cast-iron table, with suitable slots, to which the pipes are bolted, with the flanges vertical, overhanging the table, and parallel with the face-plate, in the face of which and close to the circumference, are fixed a great number of steel cutting-tools, 3 or 4 in. apart. The revolution of the face-plate causes these tools to true up the flanges of the pipes, &c., with an ease and celerity sufficiently remarkable.

The machinery in this shop is put in motion by a side-lever condensing engine of some 12-horse power nominal. This engine, although extremely old, is of very excellent design and workmanship, and performs its duty with an ease and silence we could wish to see more general. The piston rod has no parallel motion at present, the one with which it was originally fitted, having been removed from some cause, has never been replaced—a circumstance which does not seem to affect its performance in the slightest degree.

The fitting shops present the usual features—interesting enough in many ways, but which we have not space to dwell on. The machinery in them is put in motion by a beam-engine of considerable size, and supposed to be some 70 years old. The attention which it has received prevents the effects of such an extreme old age becoming manifest, and it still performs its duty as perfectly as at first; some of the brasses in the parallel motion are said to be the same originally put in. They have little resemblance to brass in appearance, being more like a dark bronze. Our readers will understand that we do not vouch for the accuracy of a statement which was made to us in perfect good faith. The entire engine is interesting from the associations connected with it, as being one of the very first constructed with an eccentric and crank, instead of tappets and a sun-and-planet wheel.

The foundry arrangements are, as may be supposed, on an extremely extensive scale, every contrivance which can facilitate the different operations being employed. There are two or three casting-houses, the largest being devoted to such works as the cylinders for the "Great Eastern;" for example, there are two casting pits of very large dimensions, so arranged that heavy castings are never raised from them. Most of the floor of the foundry is supported on iron plates and girders. The casting pits are immediately under this floor, so that we may consider the casting as being made in the basement storey. Suitable doors and a tramway are provided; so that when the casting has cooled sufficiently, it only remains to break into the side of the casting pit, which is of brick work, with three sides built solidly and one temporarily, when the casting being slightly raised by a powerful crane in the shop above, permits a low truck to be run under, when the cylinder, &c., can be wheeled to the boring machine close by with the greatest ease; the pit being cleaned and the wall built up again, is once more ready for the moulding.

There are three or four boring machines on the premises; but the one we now speak of is, we believe, the only one of the kind in England: perhaps some of our correspondents could inform us if we err? The boring-bar is upright, 14 in. in diameter, driven from below; it will bore cylinders about 13 ft. in diameter, and about the same stroke; motion is communicated from below by very heavy machinery. The bar stands under a very high and narrow arch, the width of which not being more than some 13 or 14 ft. at once limits the size of the object to be bored, and provides a means of fixing it steadily; heavy iron clamping pieces being bolted to the walls to which the cylinder can be secured. Whether large or small, the article to be bored is brought from the foundry on the proper truck, and being wheeled into place under the bar, raised by powerful tackle for the time, it is lifted off the truck by a number of small jacks, which sustain it during the subsequent process of boring. When completed, the truck is again brought into requisition to remove it to the erecting shop. At the time of our visit, one of the cylinders for the pumps to be erected at Crossness in connection with the southern outfall of the Main Drainage was having the flanges trued up. Perhaps we cannot do better than conclude this article by a slight description of these pumping-engines, which will be not more remarkable for their colossal dimensions than for the singularity of their construction. As they will not be completed for about ten months, we cannot give all the accuracy of detail we could wish; but through the kindness of one of the representatives of the firm, we are enabled to supply information which will be found pretty accurate in the main.

The entire apparatus, then, will consist of an arrangement of four steam cylinders and eight pumps, fixed in an engine-house of large size and handsome design. This house will be divided by floors into three or four storeys, the steam cylinders being on the first floor. The height from the foundations to this floor is about 43 ft., the cylinders being supported by cast-iron columns, webbed and bolted together, their cross section somewhat resembling an ordinary H-girder. The four cylinders, which are each 48 in. diameter by 9 ft. stroke, will stand, as it were, at the corners of a square, in the centre of which a noble staircase will give the means of access to the other floors. Each cylinder will have two overhead beams of cast-iron, 40 ft. long between the centres, and 6 ft. deep in the middle. The cylinders being in the centre, these beams will point towards each end of the engine-house. The two beams of each engine are mounted on a centre gudgeon, 16 in. in diameter between the beams, which will be some feet apart, and about 14 in. in the necks. The bosses which receive this gudgeon are 5 in. thick and 8 in. or 9 in. long, measuring through the beam, the middle webs of which will be 2 in. thick, with stout top and bottom flanges.

The height from the floor on which the cylinders stand to the centres of the beams will be about 26 ft.; a handsome row of cast-iron columns, elaborately decorated, affording the necessary support for their centres. The pumps will be eight in number, each 12 ft. in diameter, consisting of a suction, middle, and delivery piece, bolted together by the flanges. One pump will be erected under each of the beams, and as these are side by side so of course will be the pumps. They are placed at about half-beam, and each cylinder will have four plungers working in it, which will receive their motion through connecting rods, coupled to suitable cross-tails passing through both beams. Each steam cylinder will thus work eight plungers, the four nearest to the centre having a stroke of 2 ft. 3 in., the other four a stroke of 4 ft. 6 in. They are all 57 in. in diameter.

The suction valves will be vertical, instead of horizontal; the lower or suction pieces being cast like a circular open grate, 12 feet in diameter (equal to the full diameter of the pump) the openings, some 30 in number, affording ample water way, a separate leather valve will be suspended from the upper part of each opening; the delivery valves will be the same in principle, but the grate, instead of being circular, will be flat, and bolted on the end of a delivery piece which conveys the water to a trough placed between the pumps and common to both. We cannot give the exact height of the lift, but it will be about 18 feet we believe.

It will be remarked, that the ends of the beam project considerably beyond the pumps; to these projecting ends will be attached connecting rods, which will lay hold of cranks on the ends of shafts carrying two fly-wheels each. We thus find that each engine has one steam cylinder, two beams working eight plungers in two pumps, and two fly-wheels.

The condensers and air-pumps will be placed behind the cylinders, the latter being worked by counter-beam, which acts the part of parallel motions to the piston rods. The valves will be Cornish double-beat, worked without a cataract, by means of cams on a separate shaft which lies directly under the valve-boxes, and driven by gearing from the fly-shaft. The arrangement is one invented and frequently used by Messrs. Boulton and Watt, and is both convenient and simple. As the engines will be worked on a very high scale of expansion, with jacketed cylinders carefully lagged, and steam of a very high pressure, we may expect very economical results.

The boilers will be twelve in number, each 30 ft. long by 6 ft. in diameter. The internal flues will be 3 ft. 3 in. diameter at the firing end, reduced to 2 ft. 11 in. behind the bridge; the grates will be 8 ft. 6 in. long, one to each boiler—a length too great, in our opinion, for good firing. The flues are supplied with water-tubes on Galloway's patent. The boilers will be arranged, in two groups of six each, at either end of a very handsome boiler-house. The smoke-burning contrivances must be very successful to render the gilt ironwork, with which the top of a very gorgeous stack is to be surmounted, effective.

We have already exceeded our space, and must conclude by expressing our thanks for the courtesy which has enabled us to place these interesting details before our readers.

THE INFLUENCE OF THE BLAST IN THE QUALITY OF IRON.

When we consider the immense interests involved in the iron manufacture, it seems strange that the precise influence of the different applications of the blast on the quality of the iron produced in the blast furnace has not been investigated with the care demanded by the importance of the subject. The most eminent men of science are at variance when attempting to explain the principal phenomena resulting from the action of the tuyeres at the hearth.

If we remember that a weight of nearly 14 tons of air is consumed in an hour in some of the large furnaces—an amount nearly three times as great as that of the solid materials; the ore, flux, and fuel—it must be evident that the volume, the density, the hygroscopic state, the chemical constituents, and lastly, the temperature of the air employed, must exercise a powerful influence for good or for evil upon the products of the furnace. The action of the air will evidently not merely confine itself to the "yield" or quantity, but will also exercise an influence on the "make" or quality, of the pig.

The density of the blast employed has a considerable influence on the smelting operations, and it is principally determined by the dimensions of the furnace and the kind of fuel employed. The season of the year also requires some variation in the pressure of the air; and when its density is diminished by the heat of summer, the blowing engine has to make up the deficiency by increased speed, in order that the furnace be supplied with the requisite amount of oxygen. Before the introduction of blowing engines worked by steam, great difficulties were encountered in the use of coke and coal in the furnace. About 2 lb. to the square inch is the minimum pressure of air now employed, and this density is generally increased with the density of the fuel until in some cases it reaches 3¼ lb. to the square inch. Considerable difference of opinion still exists as to the precise shape of the tuyeres and the exact number to be employed. Mr. Truran patented in 1855 (No. 1730), "a mode of constructing nozzle pipes so that they should deliver through one tuyere two or more jets of blast, hot or cold, of like or different densities. The nozzle pipes may be divided by partitions or be double, one being within the other, so that the outer one delivers an annular jet, and the two jets may be supplied from different pipes, and be of different densities or temperatures." We do not know whether this plan has ever been tried. The blast is generally applied by means of three tuyeres, but as many as ten or twelve nozzles are sometimes used. The small tuyere system is especially adopted in Scotland. It is to be regretted that exact data do not exist as to the relative values of the two systems.

The hygroscopic state of the air, or the amount of moisture contained in the atmosphere, is another potent element of success or failure. It is estimated by Mr. Truran that about 25 tons of air are consumed per ton of metal, say dark grey pig iron, and thus, with a make of 120 tons per week, the amount of blast consumed would be 3,000 tons. According to Dalton, the air in England contains about 1·42 per cent. of moisture, in dry weather, and more than double that amount in wet weather, so that we have a quantity of from nearly 50 to 100 tons of water discharged weekly into the furnace. This is, no doubt, the explanation that there is less fuel consumed and a better quality of metal produced in winter than in summer. The increase of make is, in fact, estimated to be from 4 to 5 per cent. greater during the winter months. The chemical constituents of atmospheric air being invariably the same, it could only be by artificial means that any action on the furnace could be sought for by changing the chemical composition of the blast. Various attempts in this direction will be found recorded in Her Majesty's Patent Office. Thus we find one invention (Patent No. 6,948, Old Law), proposing to inject "pure hydrogen gas" into the blast furnace. Apart from the risk of explosion, the great expense in procuring the gas would of itself form an insuperable bar to the practical introduction of this process.

The precise effect of raising the temperature of the injected air to about 610 deg., or the use of the *hot* blast, is still a debateable point with those concerned in iron-making. The question may be briefly divided into three separate heads; the first being the influence of the hot blast on the economy of fuel, the second its action on the quality of the iron produced, the third being the commercial or trade value of the hot blast.

There is no doubt that the consumption of furnace coal is reduced by the hot blast. The saving effected varies greatly with different kinds of coal and ore. Taking the coal used in the stoves for heating the blast into account, the saving effected has been estimated at 3 cwts. of coal per ton of pig iron in Wales, and from 6 to 7 cwts. in Scotland. Various reasons have been given to account for this economy of fuel. By some it has been ascribed to an annulling of the cooling effects of the cold blast on the combustion of the furnace; by others, that a hot blast supports combustion better than a cold blast; the relative proportions of the oxygen and hydrogen on the air are, however, unaltered by the addition of heat. Mr. Truran ascribes the economy effected by the hot blast to a reduction in the quantity of coal required in the furnace from the extraneous heat thrown in by the blast, as a reduced proportion of coal to ore is always succeeded by an increased quantity of iron produced. The amount of coal required in the furnace being thus lessened, there is a less volume of blast required, the additional result being a diminished consumption of fuel in the upper parts of the furnace. Briefly stated, the economy of fuel effected may be ascribed to two causes; the reducing power of the heated blast injected at the bottom of the furnace, and the lesser proportion of carbon in the furnace to the volume of the blast.

With regard to the influence of the hot blast on the quality of the pig, we are still somewhat in the dark. There is no doubt, however, that the use of such a powerful means of acting on the furnace may, in unskilful hands, lead to bad results. Mr. Robert Mallet, in his work "On the Physical Conditions Involved in the Construction of Artillery," ascribed the "much discussed and unquestionable (?) inferiority of hot-blast iron over cold" to unnecessary heat of fusion, caused by an unskilful use of the hot blast. "Unnecessary heat of fusion injures the quality of the metal, as unnecessary heat of 'pouring' injures the quality of the casting. It does this in two ways—by the introduction of foreign earthy and alkaline bases, which greatly reduce the cohesion, and far more by the great increase of surface, produced by extreme elevation of temperature, in the disseminated plates of graphite. These, scattered through the mass, like mica or hornblende in granite, present at their innumerable planes of cleavage almost no cohesion; but these planes are, in accordance with the general law of arrangement, in planes of least pressure, found mainly to coincide in parallelism with those of the crystals of the iron itself (*i.e.*, the carburet of iron, which constitutes the metal of cast-iron chiefly), so that the total deterioration of strength is very great; and this is, in fact, the secret of the much discussed and unquestionable inferiority of hot-blast iron over cold; nothing more than the elevated temperature introduced in the blast furnace." Fully admitting that the injudicious use of the hot blast may produce the injurious effects ascribed to it by Mr. Mallet, we nevertheless differ from him in his sweeping condemnation of the process. To corroborate our opinion, we will further quote the following:—Mr. Hodgkinson, in his report on the experiments on hot and cold blast iron, made by Mr. Hodgkinson and Mr. Fairbairn for the British Association, says: "It is rendered exceedingly probable that the introduction of a heated blast in the manufacture of cast iron has injured the softer irons, whilst it has frequently mollified and improved those of a harder nature, and, considering the small deterioration that the irons of quality No. 2 have sustained, and the apparent benefit to those of No. 3, together with the great saving effected by the heated blast, there seems good reason for the process becoming so general as it has done." Respecting the specific gravity of hot blast iron, we may state that some years ago, Dr. Thomson carefully analyzed the chemical constituents of hot-blast iron, and he found, as a general result, that the specific gravity of hot blast iron is greater than that of cold-blast, and an average of several experiments showed that the hot blast increases the specific gravity of cast iron by about 1-22nd part. Dr. Thomson also found that hot-blast iron contained a smaller proportion of carbon, silica, and aluminum, than cold blast iron.

We now come to what we have termed the commercial or trade influence of the hot blast on the quality of iron.

The best English ironstone is the argillaceous or clay ironstone, and it requires the cold blast to work it in quantities. The iron produced is neither "red short" nor "cold short," and is thus never brittle, whether hot or cold. What is called "cinder" is the refuse of the puddling surface. It contains a large percentage of iron, combined with impurities that have been expelled by the puddler from the good iron, or "mine." The power given by the hot blast in extracting the iron from amongst these impurities has greatly increased the production; but the produce is rendered very inferior by an admixture of this material. It is called "cinder iron." We do not assert that the hot blast injures the quality of the iron. As we mentioned before, its precise effect has not been ascertained with any precision. But we have seen that the hot blast may be used to extract iron from any material, from the best to the worst. The cold blast can only be applied to the best ore and fuel, it cannot be used to make "cinder iron;" and thus the very name of "cold blast iron" is to some extent a guarantee as to its quality. The introduction of the hot blast has thus been a great benefit as regards *quantity* of produce, but as regards *quality*, it has offered facilities for "scamping" the work, of which, unfortunately, but too many have availed themselves. The hot blast has also been the means of permitting the ironmasters to use raw or uncoked coal, instead of the desulphurized coke. It is evident that more impurities are liable to be worked up with the iron when raw coal is employed. The Scotch coals are generally so unfit for coking that they often lose 55 per cent. in the process, and the introduction of the hot blast, by greatly economizing the coals there employed, has raised the iron manufacture of Scotland to its present importance. Within twenty years the make of iron in England has been trebled; in 1840 the total produce was a little less than 1,400,000 tons; in 1860 it was more than 4,150,000 tons. This progress, however, is more of a striking than solid character. Of the 1,400,000 tons of iron produced in 1840, 770,000 tons of this quantity was cold blast iron; of the treble quantity in 1860, only 150,000 tons were produced by the cold blast. Figures, however, do not give a true account of the produce of the iron manufacture. Mere quantity is a very rough estimate; quantity and quality combined ought to be taken into account. Double the resisting powers of the iron produced, and for many applications less than half of the quantity is required.

The value of raising the temperature of the blast is thus another point upon which much difference of opinion still exists. As we have seen, some say that hot-blast metal is greatly inferior to cold-blast, in contradiction to others who assert the contrary opinion. The exact amount of economy of fuel effected by the use of this process is another subject of dispute. No definite data exist that would warrant our drawing conclusions as to its precise influence on the molecular structure and chemical constituents of iron. We consider that this great uncertainty is a disgrace to the iron manufacturers as a body; and without overlooking the fact that a strict inquiry into the matter would, involve great expense and difficulty, we nevertheless consider it very extraordinary that the exact value of a process employed for the last 35 years, is still involved in obscurity. The fact seems to be that the manufacturers, on the one side, ignore the deductions of theoretical science; while, on the other, laboratory chemists refuse to consider the practical requirements of manufacturing on a large scale. The only means of arriving at the truth would be by the labours of a scientific commission, meeting the iron-makers on their own ground. The usual way adopted in England in encountering these questions, is to summon a host of witnesses before a Parliamentary Committee of Inquiry, and the culminating result of this expensive procedure is a voluminous blue-book, which is read by nobody. The evidence given is, no doubt, often very valuable in its way; but who is to separate the grains of wheat from the mass of chaff? This separation could only be effected by the light of science; not by orators from parliamentary benches, but by chosen men, taken from the forge, the laboratory, and the workshop.

There are many phenomena in the manufacture and use of iron, verified by the practical experience of manufacturers and engineers, which are, as yet, unexplained by science. On the other hand, many of the later important discoveries in science have not been utilized by the manufacturer. Let the ethereal spirit of science incorporate itself in the flesh and blood of practice, and the union would result in a "mens sana in corpore sano."

The questions involved in the quality of iron are no longer private questions of profit and loss and of each man's safety and comfort; by the recent alterations in shipbuilding, the national honour and security, are made to depend upon an abundant supply of good iron. In case a naval battle should ever be fought within reach of our shores, the command of the Channel would fall to the Power capable of repairing and refitting iron ships with the greatest celerity. We have seen, by the recent conflict at Charleston, how damaging a naval action is likely to be to the ships engaged; and we must not forget that the French are still in advance of us in their arrangements for docking large vessels of war. The safety and honour of England depend upon her navy; but that navy must not be dependent upon the chances of trade and the "scamping" of contractors and manufacturers. It thus becomes a question which English iron-manufacturers would do well to consider, whether the Government will not have to manufacture a portion at least of the iron required for the national defences. While wood only was used for vessels of war, the Admiralty found themselves obliged to have complete command over the supply of that material; iron now takes the place of wood, and a similar result with regard to its supply may ensue. We do not advocate that the Government should manufacture all the iron it requires; we only wish that the Government should be raised above the accidents and frauds of trade.

We often hear it vaguely stated that French iron is superior to our own, but we have no sufficient data from which we could draw a conclusion. There were certainly some very fine samples of iron from France, Germany, Belgium, and Sweden in the late Exhibition. In the Swedish Department there was a very remarkable sample of iron from that country. It consisted of the keel of an iron paddle steamer, 200 ft. long, and built at the Mortala Works. The vessel struck on a rock while steaming at a speed of eight or nine miles per hour; and although the plates bent into a most extraordinary shape, they show no fracture, and the ship arrived safely at Stockholm. A medal was obtained for this exhibit; and we remember that the question was facetiously discussed in the Exhibition as to the person who really deserved to bear away the honours. Should the medal be given to the maker of the iron, or to the builder of the ship, or rather to the pilot who tested the iron by steering it on to the rock? Seriously, however, this specimen of iron from Sweden shows what might be done with iron to ensure safety at sea; and it affords a lamentable contrast to the late disaster with the "Anglo-Saxon," which has involved the loss of upwards of 200 lives, and about £100,000 in money.

CONVERSAZIONE OF THE SOCIETY OF CIVIL ENGINEERS.

THE annual *conversazione* of the Society of Civil Engineers was held on Tuesday evening, at the society's house, 25, Great George-street, Westminster. The contents of the rooms combined many objects of interest, most of them comparatively novel. In one of the upper rooms a very complete and instructive collection of works in aluminium and aluminium bronze proved extremely attractive. The beauty of the articles fabricated from the latter alloy leaves no doubt that, as far as appearance at least goes, a perfect substitute for gold has at length been discovered—one, too, which bids fair to excel in truthfulness and beauty of appearance any of the alloys which have hitherto rendered the imitation of silver a task so much easier than the imitation of gold. The extreme lightness of aluminium, combined with a fair amount of richness, points it out as extremely suitable for the construction of such articles as scales for mathematical instruments, &c. The alloy of 10 parts of aluminium with 90 parts of copper seems likely to prove one of the most valuable materials we have yet discovered for the construction of ordnance.

In the large hall, we noticed a very fine micrometrical instrument by Whitworth. The standard calipers also exhibited seem to be really useful instruments which no engineering establishment should be without. We would call attention to a comparatively recent invention, not so generally known as it ought to be. We mean buckled plates—a very fair specimen of which, suited for safe doors, stood at one side of the room. These plates, although very light, are of immense strength, and would be found very suitable for floorings, or any other purposes where large surfaces are required to sustain heavy weights without much trussing. We have an idea that a very excellent steam boiler could be constructed by the aid of this very simple invention.

Models of Price's patent railway signals stood near; but from want of the necessary information, which was afforded neither by an attendant nor suitable papers, we are unable to say aught of its merits. Wright's permanent way sleepers, close by, appeared to contain a good idea which may be further developed at a future day.

The models of shipping were not the least interesting objects shown. Amongst others, we noticed beautiful models of the "Northumberland" and other iron-plated ships. Edwards's "shoal water indicator" seems likely to prove useful. It consists of a long bar, which can be projected from the ship's bottom, near the keel, to a depth of a couple of fathoms. It is steadied by suitable guys, and by very simple arrangements rings a bell placed on deck the moment the vessel takes water so shallow as to permit the projecting bar to touch the bottom. It seems likely to prove a substitute for the lead in many instances.

Muntz's Patent Metal Company exhibited one of their recent inventions for sheathing iron ships. The principle is as follows:—A large number of holes of small diameter are drilled about ¼ inch deep in the iron plates forming the ship's side. A sheet of india-rubber is then so applied that it not only covers the iron perfectly, but also enters the holes, completely stopping them up. The sheathing plates are then applied outside of the india-rubber, and are secured by suitable nails or screws driven into the india-rubber plugs which fill the holes. The principle seems strange, but there is no question that the sheathing was attached in a first-class manner to the plates exhibited. We much fear that the expense of drilling the holes would be found a very serious item in carrying out the invention on a large scale.

Grivel's "self-acting skid" is, we believe, correct in principle and extremely simple; by means of it the train cannot run backwards should a coupling break. Its use might prevent such accidents as that on the Oxford and Worcester railway. We feel little doubt something of the kind has long been wanted. Archbut's new theodolite also shows numerous advantages which civil engineers will not be slow to appreciate. The telescope can easily be rotated on its longitudinal axis, so that the errors of collimation can easily be corrected. A slightly conical enlargement on the centre of the telescope rotates within a strong conical ring, to the inside of which it is accurately ground, and fitted much as an ordinary tap is to its outside casing. The workmanship is excellent, and shake is impossible; even after years of wear it is only necessary to draw the conical band further into the ring to make all tight as at first.

It would be quite out of the question to attempt even an enumeration of the many novelties shown. We believe there has rarely been a *conversazione* of the society which has proved more generally interesting. The attendance was very large, embracing most of the leading scientific men of the day. The arrangements for securing the enjoyment of those present were, as usual, perfectly successful; and few who were there can look back with any feeling but that of pleasure to the scientific reunion, which has been a leading incident of the week.

STEAM FIRE-ENGINE COMPETITION.

OUR readers will have seen, by a notice in our advertizing columns, that the trial of Steam Fire Engines, originally fixed to take place on the 1st of June, is deferred to the 1st of July. The committee have not vouchsafed to give any reason for this unexpected postponement; it is pretty well understood, however, that "The Favourite" could not be got ready in time. Foreigners were invited to enter the lists with English manufacturers; and two steam fire-engines have already arrived in this country from America, under the idea that the trial would come off at the time originally appointed; it is to be hoped, therefore, that ready or not ready, no further postponement will be permitted.

Much dissatisfaction having been expressed at the manner in which the Exhibition trials of fire-engines were conducted, in Hyde-park last summer, it is to be hoped that upon this occasion some well-defined programme, to be mutually agreed upon by the Prize Committee and the competing manufacturers, will be laid down, and rigidly adhered to; and that nothing like partiality on the part of any member of the committee, or sharp practice on the part of any competitor, will be permitted.

It has been remarked that the hon. secretary of the committee has hesitated to give definite explanations, when applied to, upon the ground that he is only one of many who compose the Prize Committee; but, by virtue of his office, he is the organ of the many, and ought to be prepared to answer all inquiries that may be addressed to him.

It is to be hoped that the canvas catch-water receptacles, used in Hyde-park last summer, will not again be employed; they are bad in principle—worse in their construction and application. Instead of an orifice opening into an enlarged chamber, it opened into a diminishing one, the consequence of which was, that a large proportion of the water thrown forcibly into the hoods rebounded out again—the more compact and powerful the jet, the greater the loss from this cause. It was noticed that while one of the broken jets lodged the whole of its spray within the receptacle, a more compact and solid jet rebounded backward, almost on to the branch-man. A scientific writer who was present gave it as his opinion that, "the canvas hoods afforded no fair test of the quantity of water thrown, and the results were hardly worth recording. In many of the trials, more than half the water, apparently, fell outside of the hoods and upon the ground, and in others the discharge from one engine was blown in spray into the gauge-box of a rival engine."

Such an experiment, made under the most favourable circumstances, could not possibly be either conclusive or satisfactory, involving, as it inevitably does so many disturbing elements.

The form, material, and lay of the hose, the more or less perfect form of the nose-pipe, the force and variation of the wind (especially if crossing the line of fire), and, above all, the skilfulness or awkwardness of the branch-man, so largely influence the results, that no positive or trustworthy data can be founded upon such trials.

At no previous trials of fire-engines were there so many scientific men or experienced firemen present, as in Hyde-park in June last, one and all of whom condemned the canvas hoods. Whatever programme may be decided upon, one thing suggests itself as desirable upon the forthcoming competition—viz., that in order to ensure even-handed justice, as between the prize-givers and the competing parties, two umpires and a referee should be chosen, to whom all disputed points could be referred.

BRIEF BIOGRAPHIES OF INVENTORS OF MACHINES FOR THE MANUFACTURE OF TEXTILE FABRICS.

By Bennet Woodcroft, F.R.S. London: Longmans. 1863.

It is natural that we should feel interested in those from whom we have derived benefits, which are all the greater because they are so universal in their application that they have almost ceased to be regarded as matter worthy of attention. Next in importance to the air we breathe, and the food which supports us, we must rank the materials which clothe us. Textile fabrics have long been a necessity of man's life, without which we should cease to exist. True, their origin dates back to the remotest period; but the mere possession of the means of supplying any article universally required is of little avail, unless it can be supplied at such a moderate price as will place it within the reach of every class requiring it. Cotton goods would little avail us if they cost a guinea a yard. Blankets would be out of the reach of many at £20 a pair. Yet, were it not for the facilities of production placed at our disposal by the individuals whose short biographies we have here before us, such prices would be the rule. Twenty years before Parliament granted £5,000 to Crompton, Mr. Pollard, of Manchester, spun yarn of 278 hanks to the pound weight (equal in length to more than 132 miles) upon one of Crompton's mules from cotton worth 5s. a pound, grown in the island of Tobago; he sold this yarn for 20 guineas a pound to the Glasgow manufactures to be woven into muslins intended to compete with Indian fabrics that were selling at 10 and 12 guineas a yard. Little more than 70 years have elapsed, yet now the finest muslins are within the reach of the most moderate income.

Mr. Woodcroft's little volume supplies a want long felt. Much general information regarding the lives of men who have conferred lasting benefits, floats about in a loose way, which renders it difficult to get at; here we find a valuable mass of information condensed and rendered easy of access. The merit of the book speaks for itself; and we give the life of one not generally known even by name, Joshua Heilmann as a specimen.

To the nine individuals whose biographies Mr. Woodcroft has given us, we are mainly indebted for the rise and progress of the cotton manufacture, a progress which we cannot illustrate better than by using Mr. Woodcroft's own words. "In 1760, at the accession of George III., the entire value of cotton goods manufactured in England was about £200,000 a-year. In 1860 it was estimated at upwards of £52,000,000. In 1772 British calicoes were made to the number of 50,000 pieces. In 1816 upwards of 1,000,000 pieces were manufactured. 1750—Population engaged in cotton manufacture about 20,000. 1801—Persons engaged about 80,000. 1823—10,000 steam looms in Great Britain. 1862—Their number was 399,992, driven with a power of 297,000 horses, and employing 451,000 work people, in 2,887 factories, containing 30,387,457 spindles." But for Crompton, Cartwright, Kay, Roberts, &c., we should never have had such facts as these.

We cannot peruse the work without a sigh. It is a record of genius unrewarded, unsympathized with in its struggles, perishing miserably, the victim of an ungrateful world. It is a record sufficiently powerful to dissuade any but the most determined from venturing on the thorny path of invention, which seldom indeed leads those who enter on it to a result which can encourage others.

Joshua Heilmann

Was born at Mulhouse, France, on the 19th of February, 1796. Having received a commercial education, he commenced an apprenticeship in his father's office, in 1811, where he laboured for a couple of years, employing his spare time in making drawings of machines. In 1813 he was employed for some time in his uncle's banking-house in Paris, where he devoted his leisure hours to mathematical studies. In 1815 he performed the duties of cashier and book-keeper in his father's house.

In 1816 his friends determined to establish a small cotton-spinning factory; and his uncle, Risler Heilmann, placed young Heilmann for a short period in Messrs. Tissot and Rey's spinning factory at Paris. During this year of sojourning in the capital, he employed his time most industriously. Having entered as a student at the Conservatoire des Arts et Métiers, he attended a special course of lectures on physics. He took lessons in turning, almost daily, from a toymaker, and spent every Thursday in studying the machines of the Conservatoire; his Sundays were employed in drawing the machines at Messrs. Tissot and Rey's factory; and he visited the workshops of Paris to collect information on the subject of various manufactures.

On returning to Mulhouse, in the year 1817, it was proposed that he should be employed in the small factory of Messrs. Heilmann and Son; this arrangement, however, did not take place, in consequence of his family projecting the establishment of a spinning-mill at Vieux-Thann, in which he was to undertake the mechanical department. At that period there did not exist in Alsace an engineering establishment capable of making the required machinery, so that upon Joshua Heilmann, at the age of twenty-two, devolved the responsibility and labour of founding, unaided, a spinning-mill of 100,000 spindles. He made all the drawings, superintended the construction of all the machines, and succeeded in setting the mill to work before 1819.

For some years he superintended the factory of Vieux-Thann, and during this period his leisure time was devoted to the improvement of machinery connected with textile and other manufactures. In 1821 he projected the establishment of a foundry and a machine-shop in connection with it, but this project was abandoned. He then undertook the construction of two windmills for working lifting-pumps; one for the irrigation of the plains of Oxenfeld, and the other for the environs of Mulhouse.

In the year 1823 Heilmann began to occupy himself with power-loom weaving, and he invented several improvements in looms for weaving cotton goods. A number of looms upon his plan having been set to work in the establishment of Vieux-Thann, arrangements were made with Messrs. Risler, Brothers, and Dixon, to introduce the invention into public use; and, on the 10th of June, 1824, a French patent was obtained in the names of those gentlemen. The improved looms were noted for their simplicity and economy of manufacture.

Heilman's attention was directed, in 1826, to the improvement of preparation machines used in cotton-spinning.

On the 27th of March, 1828, he obtained a French patent for an improvement in roving machinery, which, however, did not find favour with spinners.

The establishment of Vieux-Thann having been affected by various commercial crises, passed into the hands of strangers, and Heilmann rejoined his family at Mulhouse. The idea of producing an embroidering machine now occupied his attention. He learnt the art of embroidering from his wife, and in six months' time he had constructed a machine in which twenty needles were caused to embroider simultaneously. For this machine he obtained a French patent on the 9th of March, 1829; and, on the 2nd of May following, an English patent for the invention was granted to Henry Bock, to whom it had been communicated by the inventor. One of these machines was exhibited at the Exposition of 1834 in Paris, and the central jury awarded a gold medal to Heilmann, who obtained also the decoration of the Legion of Honour as an acknowledgment of his ingenuity.

On the 8th of April, 1830, he secured a patent in France for an improved loom, in which rotary or wheel temples were used for keeping the fabric distended; but he soon abandoned this invention.

In the year 1833 he invented a machine for measuring and folding fabrics, which was also exhibited in the Exposition of 1834. Of these machines he constructed about a hundred. A French patent for this invention was dated February 3, 1834.

In the same year the employment of the "bobbin and fly frames" of the English spinners increased more and more in the French factories. Heilmann directed his attention to them, and invented some improvements, for which he obtained a French patent, dated June 30, 1834, and a French patent of addition for further improvements on the 22nd of August following. Heilmann's improved machine was not well received by the French spinners; he therefore came with a model to England, and soon sold his invention; but the house by which it was purchased did not work the machine.

About the year 1835 weaving again formed his favourite study; and he devoted himself to the improvement of the manufacture of silk stuffs. The project was favourably entertained by influential persons interested in the manufacture, who placed at his disposal the capital necessary for carrying out his inventions on a large scale; and in a short time 120 looms, on the improved plan, were set to work by Heilmann at Mulhouse, and a like number at Avignon. In order to effect the improvements in the manufacture of silks, he introduced a series of improved preparation machines, including a weft-winding engine, for which a French patent was obtained on the 23rd of February, 1838, in the names of Messrs. Nicholas, Koechlin, and Brothers. Unfortunately, the whole management of this undertaking had to be borne by Joshua Heilmann, who could not make it commercially successful, and, therefore, it was abandoned. He likewise devised a method of communicating motion to machines by means of iron wires, in place of straps, and put it in operation in Messrs. Koechlin's manufactory at Mulhouse.

He next invented a loom for weaving simultaneously two pieces of velvet, or other piled fabric, united by the common pile to both, and also an improved knife and traversing apparatus for separting the two fabrics by cutting the pile through the middle. For these inventions, together with the weft-winding engine before referred to, an English patent was obtained on the 19th of January, 1841, by Frederick Steiner, on behalf of the inventor. A patent was obtained in France for the loom and cutting apparatus, dated May 18, 1841, by Heilmann, in his own name. For several years he made great exertions to get these inventions into use in England, but did not succeed.

In the year 1843, in concert with Mons. J. J. Bourcart, he again took up a subject previously entertained by them, of combing long-stapled cotton. To the full development of this project Heilmann devoted the remaining years of his life. He sought not merely a simple preparation machine for cotton, but a new system of machinery for the preparation, by combing, of various textile, materials used in the industrial arts, such as cotton, wool, silk waste, flax, hemp, &c. The perfected machinery formed the subject of patents obtained in France, December 17, 1845, and in England, February 25, 1846.

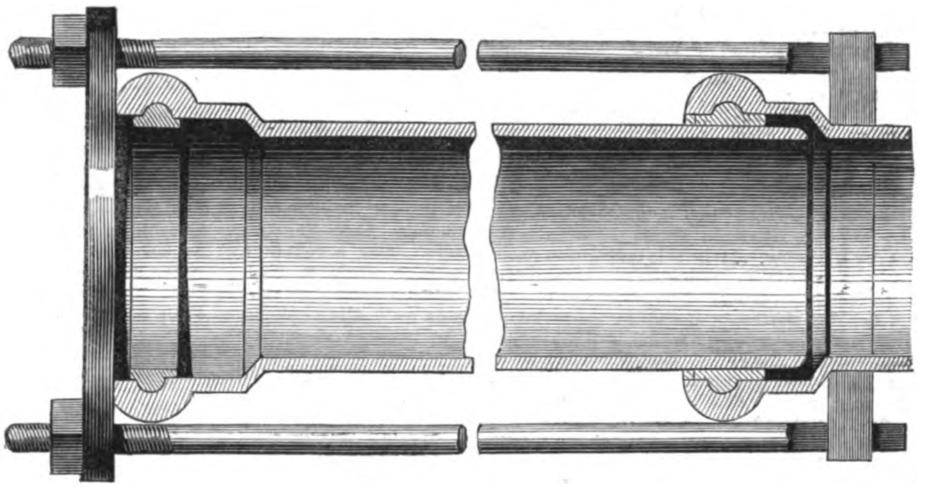
The nature of the machinery may be explained by the following extract from the English specification, in which the invention is stated to consist:—"Secondly, in a new combination of machinery for the purpose of combing cotton, as well as wool and other fibrous materials; into which machine the fibres as they come from the dressing machine are introduced in a lap, sliver, or fleece, which is broken asunder, and the fibres are combed at each end, and the long and short fibres are separated—the long ones being united in one sliver, the short ones in another; and they are passed out of the machine thus separated, ready for drawing, roving, and other subsequent operations." Mr. Heilmann told the writer that the most novel and valuable part of this machine, which he had long unsuccessfully endeavoured to obtain, was ultimately accomplished by carrying into mechanical operation a suggestion that occured to him whilst watching his daughters comb their hair. He was at the time meditating on the hard fate of inventors generally, and the misfortunes which befell their families. This circumstance being communicated to Mr. Elmore, R.A., was embodied by him in a picture, which was exhibited and greatly admired at the Royal Academy in 1862.

The inventor lived to see his combing machinery in full practical operation in France; but he was not spared to extricate himself from the debts he had incurred in giving this his most valuable invention to the world. He expired of consumption, on the 5th of November, 1848, at Mulhouse, where his remains were interred.

His executors introduced this machinery into England under the protection of Heilmann's English patent; and novel and useful as it was, it would have been appropriated in Yorkshire to private purposes had not the strong arm of the law interposed, and thereby allowed Heilmann's ruined family to reap solid advantages from machinery which has proved of incalculable benefit to this country.

The draft specification of his combing machinery, written by himself, is in the possession of the writer, at the Patent Office.

ROBBINS, KEAN, AND CASE'S PIPE-JOINT.



ROBBINS, KEAN, AND CASE'S PIPE-JOINT.

A PATENT has just been obtained by Messrs. R. C. Robbins, J. M. Kean, and H. L. Case, all of Jersey City, for "an improvement in the construction of the joints of cast-iron gas and water mains and other pipes," as illustrated in the accompanying engraving, and which they describe as follows:—

This improvement in the construction of the joints of cast-iron and other pipes, consists in making such joints by forming grooves or recesses around the interiors of the sockets or larger ends of the pipes, making the smaller ends slightly taper, casting rings of lead or other soft metal or alloy within the aforesaid grooves or recesses before putting the pipes in the ground or into the places they are to occupy, and afterwards drawing or forcing the taper smaller ends tightly into the rings.

The socket has an enlargement on the end, having an appearance on the exterior of a very large bead, instead of the small one usually formed thereon; and in the interior of the socket at this enlargement, we form the hollow before mentioned. To fill this hollow with the lead necessary for the junction, we bore, or otherwise form, a hole through from the outside, and place a former mould core, one part of which fits in the socket, and while the remainder is reduced to the size of the pipe end to be placed therein, a disc of india-rubber material, fitting the interior of the socket, is placed on the end of the former; this, with the shoulder of the former, limits the breadth of the annular form of lead to be run into the socket, which occupies a position somewhat similar to the lead ordinarily introduced for such junctions, which is much less in breadth, and enlarges into the recess before mentioned. The former is readily removed by detaching the india-rubber disc, and the lead remaining in place. The smaller ends of the pipes are made taper for a short distance, and, in order to cast these taper ends, and portions of the cylindrical exteriors of the pipes as true and smooth as possible, the ends of the moulds in which they are cast should be composed of a ring of cast iron which has been bored out perfectly true and smooth; this ring is placed on the core before placing the latter on the mould, and, by adjusting this ring along the core, the pipe may be cast longer or shorter as desired. In this way the lead, or other metal or alloy used, may be put in place before the joint is made, which is performed by simply forcing the small end of the one pipe into the lead lining of the socket of the adjoining pipe, which may be done by any suitable apparatus. An apparatus we use is very simple, consisting simply of two half-rings, which is placed behind the socket of the joint to be made, and apply eyes or loops formed on two long rods, which keep the half-hoops together; the other ends of the rods have screws and nuts jointed to the end of the pipe to be forced into the socket; a bar stretched across the end of the pipe receives the pressure of the nuts and strain exerted to force the joint home. The mouth of the socket in front of the groove or recess, may be made somewhat larger than the back portion of the interior of the socket, to permit the introduction of a caulking tool, to caulk the ring if at any time necessary.

MOLECULAR CONSTITUTION OF STEEL.

KARSTEN observed that by the action of acids upon soft steel, a graphitic substance is obtained as a residue, which is not obtained by the action of acids upon hardened steel. This substance he represented to be a definite carburet of iron FeC^4. Berthier also stated that cast steel contains another carburet, CFe.

M. Caron* infers, from the results of numerous analyses, that these carburets are probably mere variable mixtures of carbon and iron, in which the iron is protected mechanically by the carbon from the solvent action of the acid.

He has experimented upon steel in three different conditions—

1. Steel as it comes from the cementation chambers.
2. The same steel hammered for a long time.
3. The same steel hardened.

By the action of hydrochloric acid on these three kinds of steel, the quantities of graphitic residue obtained are very different, being for 100 parts as follow:—

	Graphitic residue.	Carbon.	Iron.	Silicium.
Ordinary steel	1·624=	0·825	0·557	0·242
Hammered steel	1·243=	0·560	0·445	0·238
Tempered steel	0·240=	trace.	trace.	0·240

These results show that the effect produced by tempering is to some extent produced by hammering, and the quality of the steel appears to improve in proportion as the carbon is intimately combined with the iron.

In the same manner forging, which improves the quality of steel, also reduces the quantity of carbon that is separated by solution in acids. Rolled steel gives more graphite than hammered steel. The influence of heat in this respect is the reverse of that produced by hammering and tempering, and re-heated steel does not recover its primitive quality, or its chemical properties, as regards acids, until after it has been hammered or tempered.

White pig iron presents the same variation in the quantity of carbon that it contains in a free state, and the duration of the annealing. However long this may last, there is still some carbon remains uncombined.†

In the tempering of steel, the rapid cooling has a compressing influence upon the metal, almost instantaneous, and presenting the closest analogy with the blow of a hammer.

---

* *Comptes-Rendus*, lvi., 43.

† *Comptes-Rendus*, lvi., 211.

A bar of steel rapidly heated to the temperature requisite for tempering, and immediately plunged into cold water, underwent the following alterations of bulk:—

	Before Tempering.	Red hot.	Tempered.
Dimensions in centimetres	20·00	20·32	19·95
	1·00	1·03	1·01
	1·00	1·03	1·01
Volume, ditto	20·00	21·557	20·351

The effect produced by the tempering consists in a rapid approximation of the particles acting in every direction. It is this concussion which M. Caron regards as producing the combination of the iron and carbon. The increase of temperature has the effect of dilating the metal and giving to the molecules a mobility necessary to enable them to unite; the sudden cooling bringing them rapidly together, causes combination.

A bar of iron heated to bright redness was briskly hammered on an anvil covered with finely-powdered carbon; when it had cooled to a dull red heat, it was suddenly plunged into cold water. Some parts of the bar were then found to have been converted into steel at the surface, and resisted the file. The same iron heated to redness, and cooled in the midst of charcoal without being hammered, did not present any trace of being converted into steel when tempered in the same manner.

Hammering does not effect so complete a combination as tempering, because it causes the concussion of the particles only in one direction, while the sudden cooling in water causes their concussion in every direction simultaneously. Moreover, the temperature of the metal after hammering tends to destroy the combination that has been effected by it. On the contrary, the metal being quite cold after the concussion produced by plunging it into water, no further reaction is possible, except by heating the metal again.

Reaumur* and Rinman† state that the volume of tempered steel is 1-48th greater than that of soft steel. Karsten,‡ on the contrary, says that it is not quite certain that all steel expands by tempering, and becomes of less density. In M. Caron's experiments on this subject, he heated the steel in earthen tubes filled with hydrogen. A bar of hammered steel, 1 centimetre square and 20 centimetres long, was tempered, and found to be reduced in length to the extent of half a millimetre; the other dimensions were increased 0·06 mm.; the density was rather less than before, 7·796 in place of 7·817. These differences being small, the experiment was repeated several times with the following results:—

	Before tempering.	After tempering 10 times.	20 times.	30 times.
Dimensions in centimetres	20·00	19·50	18·64	17·97
	·94	·96	·97	1·00
	·93	·96	·97	1·00

Hence it appears that the reduction in the length of bar after thirty temperings was nearly one-tenth. The diminution in length was not due to oxidation, and the sharpness of its edges was retained almost entirely. The bar was then cleaned, and the density found to be 7·743; consequently the volume had increased.

Similar experiments with a great number of bars of steel gave like results, and M. Caron concludes, that in tempering, steel bars are reduced in length, while the width and thickness augment in the same proportion as the density is reduced.

The opinion expressed by Karsten, and the differences observed in steel of different manufacture, induced M. Caron to continue his examination to drawn and sheet steel, with the following results:—

	Dimensions before tempering.	Dimensions after tempering.
Round drawn bar steel .	20·05	19·98
	1·16	1·16
Rolled steel (German plates) . .	20·00	20·45
	1·51	1·51
	3·70	3·70

These results, and those already given, show that in tempering—

1. Hammered steel bars are reduced in length.
2. Round bars partly hammered and partly drawn are scarcely altered in length.
3. Plate-steel increases both in length and width.
4. In all cases the density diminishes—a result which agrees with M. Regnault's observation, that soft steel is denser than tempered steel.

It appears, therefore, that a bar of steel may, in tempering, change its dimensions in a different manner, according to the mode of its manufacture. This accounts for the fact that slender articles, such as files, become twisted; this would naturally be the result if, in forging, one side were more hammered than the other. At the moment of immersion in water, the side that has been most hammered diminishes in length more than the other, so giving rise to the defect.

The effect of the sudden cooling of steel in tempering, may be compared in other respects to the effect produced by the blow of a hammer. Thus, the more sudden it is, the more considerable is the corresponding force exercised, and the greater will be the hardness. This may be inferred from the following table, representing the time of cooling of a bar of steel, and the corresponding degrees of temper produced in the metal:—

	Water.	Water.	Water with 10 per cent. dextrine.	Alcohol.
Original temp. of the liquid	10°	50°	10°	10°
Final temp. of the liquid...	22°	61°	23°	30·5°
Time of cooling	4''7	11''3	13''2	21''7
Degree of temper...............	good.	slight.	very slight.	none.
Shortening of the bar.........	1-28	1-147	1-172	insensible.

The result of a great many experiments with various liquids—mercury, saline or acidulated solutions, water covered with oil, or containing in solution mucilaginous or syrupy substances, oil, &c.—appeared to indicate that the hardness and other characters produced by tempering are inversely proportionate to the square of the time of cooling.

M. Deville* regards these results as accordant with the results of his observations on the remarkable physical and chemical properties communicated to substances by rapid cooling, or, in other words, the excessive proportion of latent heat, or heat of constitution, they retain when suddenly cooled.

Those observations showed that substances might, in this respect, be divided into two very distinct classes.

One class comprises sulphur, selenium, silicium—or rather its compounds, silica and silicates—and the experiments of Jacquelain, Lavoisier, and Silliman justify the addition of carbon to these. The other class includes lead, tin, bismuth, and probably metals generally. The substances of the former class are "superfusible," and capable of being tempered, and acquiring the vitreous or amorphous condition. The substances belonging to the second class present the same molecular condition after cooling either rapidly or slowly, their density remaining constant.

M. Deville considers that the results obtained by M. Caron may be explained by regarding iron and carbon as belonging respectively to these two different classes. Those results and Karsten's show that iron and carbon combine at a high temperature; that if the compound is allowed to cool slowly, the constituents crystallize separately, the mass acquires a maximum density, and acids effect its separation into iron and a graphitic substance. On the contrary, when the cooling is sudden, the carbon remains in a state of superfusion, and communicates the property to the compound containing it in the same manner that silica communicates this property to alkalies and metallic oxides.

When the proportion of carbon is larger than in steel, rapid cooling gives white pig iron, and slow cooling grey pig iron.

From this point of view, steel may be compared to glass, which becomes divitrified when it is heated, or to sulphur, which becomes octahedral sulphur when heated to near 100° C. It is, indeed, worth inquiry whether in the tempering of steel, the effect produced is not absolutely similar to that observed in tempering sulphur; that is to say, the production of two distinct layers, one superficial and very thin, the other internal, and corresponding respectively to insoluble and soft sulphur.

In any case, the sudden approximation of the molecules determined by tempering, and compared by M. Caron to the effect of hammering, maintains permanently a greater distance between the molecules than their gradual approximation by slow cooling.

As regards heat of constitution, there is in such a case a retention of a certain quantity of heat, which is, on the contrary, disengaged during slow cooling. This is the condition which M. Deville terms superfusion.

In the case of the different kinds of allotropic sulphur, it has been possible to some extent to measure the quantity of heat evolved during the transformation of soft sulphur and insoluble sulphur into octahedral sulphur. In the case of steel, the density and calorific capacity afford only indirect evidence of the existence of similar conditions.

M. Deville considers that not only carbon is capable of converting iron into white pig iron or steel, but that, in accordance with the views above expressed, any of the electro-negative elements placed in the same condition as carbon would have that effect. Nitrogen he considers to be especially suited for this purpose.—*Chemical News.*

THE SOILS OF ENGLAND.

(*Concluded from page* 390.)

The property of soils to store up food for plants is thus not confined to one particular kind of fertilizing matter, but it applies to them all, and manifests itself in a way which is modified by the composition of the soil.

In these, and in all other experiments which I have since made, the ammonia, potash, phosphoric acid, and other fertilizing matters contained in a solution were never completely absorbed by any soil, however weak or concentrated the solutions were that were filtered through the soil. Indeed, if the solution of saline matters which are brought into contact with soil are very dilute, scarcely any absorption of ammonia, potash, or phosphoric acid takes place.

Sewage of towns, on account of the very diluted condition in which this liquid is usually found, in percolating through a soil scarcely leaves any of its soluble constituents in the soil in a fixed or less soluble form, although the soil possesses in a high degree the power of absorbing and retaining soluble fertilizing matters.

All soluble saline matters, however useful or necessary they may be, impede the rapid growth of plants if they are presented too abundantly or in too concentrated a solution to the roots of plants. One of the functions of the soil appears to be to transform such readily soluble compounds into combinations so little soluble in water, that they pass in common life as insoluble, but which are still sufficiently soluble to supply the growing plant with the necessary amount of mineral food in a state of solution.

This beautiful power of soils thus not only effectually prevents the waste in fertilizing matters which heavy rains would otherwise occasion, but also rectifies in a great measure any misapplication which may be made of concentrated soluble fertilizers.

The power of soils to modify manuring matters depends in a great measure on the chemical composition of the soil, and also on the concentration of the liquid and the quantity of soluble fertilizing matters which is incorporated with that portion of the soil which is penetrated by the roots of plants. Hence the effect which one and the same manure is capable of producing varies greatly in different soils, and also with a rainy or dry season.

The office of the soil is not merely to supply mineral food to plants, but also to manufacture, so to say, crude food into a condition fit for assimilation; to prevent injury to the living plant by too large an accumulation of soluble matters in the surface soil; to store up for future use such an excess; to diffuse it equally in that portion of the land reached by the roots of the plants; and to modify it in conformity with the requirements of our crops, in a manner differing with each description of land.

* *Comptes-Rendus*, lvi., 325.

Respecting the causes of the absorbing properties of soils, the opinions of chemists are divided. Liebig regards this power as analogous to, if not identical with, the physical power which charcoal possesses in retaining colouring matters, and consequently considers the soluble fertilizing matters which are brought into contact and absorbed, either wholly or partially, by the surface soil, as present in what he calls a physical state of combination.

Professor Way, on the other hand, believes the absorption to be due to the presence of certain double silicates of alumina in the soil. Thus, for instance, the double silicate of alumina and soda when brought into contact with lime, according to Way, parts with its soda and takes up lime. When the double silicate of alumina and lime thus formed is brought into contact with magnesia, lime passes into solution, and a double silicate of alumina and magnesia is formed; this in its turn is decomposed by a salt of potash; and the double silicate of alumina and potash by a salt of ammonia; thus finally, a double silicate of alumina and ammonia is produced.

Such displacements indeed took place on repeating Way's experiments; but when a preparation made after Professor Way's directions, and containing silica, alumina, and ammonia, is mixed with an excess of a solution containing a salt of potash, ammonia passes into the solution and potash is absorbed by the preparation. From a similar preparation containing silica, alumina, and potash, an excess of a solution of a lime salt removes potash, and the lime becomes absorbed.

But as in no case I have been able to notice a substitution of one base for another in equivalent proportions, and no double silicate of a definite composition can be produced by Mr. Way's plan of operation, and the existence of such definite compounds in soils has never been demonstrated, I would suggest a different cause or causes which are in operation when potash, ammonia, and other fertilizing matters are fixed in the soil.

The absorption of soluble fertilizing matters by soils, I believe may be readily explained by a reference to well-known chemical facts. The absorption of soluble phosphates or phosphoric acid is readily explained by the affinity which carbonate of lime, oxide of iron, and alumina, which occur in every fertile soil, possess for phosphoric acid.

In the absorption of potash and ammonia, I am of opinion that the hydrated oxides of iron and alumina in the soil have a great share. Like all bases of the formula $R^2 O^3$, these oxides in a hydrated condition, in relation to strong alkalies, are weak acids, in consequence of which they have a tendency to unite with potash or ammonia under favourable circumstances.

The absorption of ammonia, potash, and of phosphoric acid by soils accords with well-known chemical facts; and as these substances are by far the most important fertilizing agents, it may be maintained that the principal absorptive properties of soils are due to chemical and not to purely physical causes.

The mechanical or physical condition of soils, however, affects very materially their productive powers; and it is only in a soil in a proper physical condition that the chemical properties can properly manifest themselves.

Great stress is laid by Liebig, as it is indeed by all good farmers, on the mechanical cultivation of the land. Liebig directs special attention to the physical state of combination, as he calls it, in which the mineral matters must exist in the surface soil, in order that they may be of utility to the plant. Whatever may be the precise meaning of the term "physical state of combination," or whether we assume that mineral food must be presented to plants in solution, or in some other mysterious form variously represented in Liebig's "Laws of Husbandry," certainly mineral food cannot be of any service to plants except it be present in the surface soil in an available form. The word "available," perhaps conveys as correct a meaning as the more novel and less graphic expression, "physical state of combination."

In such an available condition mineral food cannot be brought into the surface soil, unless water can freely percolate through the land. This is effected by various mechanical means, such as subsoiling, trench-ploughing, surface stirring, &c. By all these means the porosity, and with it its capillary attraction, is improved. As soon as continued dry and warmer weather sets in and vegetation makes a fresh start, the mineral food prepared previously in the lower strata of the soil begins to move in an upward direction. With the evaporation of moisture from the surface, fresh food is conveyed into the surface soil by capillary attraction, and thus the fertility of the latter is again restored. The appearance of nitre, and similar saline efflorescences on the surface of soils during long-continued dry weather, sufficiently shows the display of capillary attraction.

This explains why the exhausted surface of land abounding at a greater depth in mineral riches, remains unproductive when it rests on an impervious undrained subsoil; why winter-fallow does not materially restore the fertility of the surface if it is not accompanied by repeated ploughings, subsoiling, and similar mechanical operations, tending to increase its porosity; and why in a well-cultivated clay soil vegetation is most luxuriant when the intervals between wet and dry weather are neither too short nor too prolonged.

Looking at the different soils of England, we meet with two extremes—naturally barren sands and rich fertile clays. Between these two extremes we find all gradations: some partaking more of the characters of the one class, and others more of the properties of rich clay land.

Many originally barren soils, by dint of abundant manuring, the cultivation of green crops, which are consumed on the land by fattening sheep, by the purchase of oil-cakes and other kinds of concentrated food, and the increased production of home-made manure, have been brought into a high state of cultivation. But although in this improved condition they yield large crops of wheat, barley, and roots, it can hardly be said that their permanent fertility has been materially increased. Left to themselves, they soon again become unproductive, and therefore require constantly a renewal of those constituents which are removed in the crops grown on such land. High farming, in reference to light sandy soils, restores to the land infinitely more mineral matter of the most valuable kind than is removed in the corn-crops sold off the farm. As regards such land, high farming cannot therefore be called a system of robbery.

Deep, rich clay-soils, on the other hand, often contain, practically speaking, an inexhaustible supply of potash, phosphoric acid, magnesia, soluble silica, &c. The amount of mineral matter taken from such land by a long succession of the most exhausting crops is quite insignificant in comparison to that existing in 12 or 18 in. of soil.

The actual state of fertility of land, however, does not so much depend upon the absolute amount of mineral plant-food in a given depth of soil, as upon the proportion which exists in the surface in an available condition, or as Liebig calls it a "physical state of combination."

Mechanical cultivation, the judicious use of ammoniacal manures, the restoration of particular mineral matters which, like phosphoric acid, are most speedily removed from the surface and alternate cropping, are some of the means of repairing the fertility of the surface.

On light sandy soils, deficient in potash, phosphoric acid, and other mineral matters, ammoniacal salts or nitrate of soda should be avoided; but on soils abounding in mineral food, such dressings may be used with great advantage,

Ammoniacal salts certainly increase the solubility of mineral matters and promote their diffusion in the soil. Still, making all allowance for this, they appear to have a special effect on some crops and not on others. Thus cereals are improved by them, but not clover or beans. In a series of most valuable experiments by Messrs. Lawes and Gilbert, the plots continually manured with mineral matters produced only a slightly increased crop of wheat, nor was the produce increased to any extent in those years in which mineral manures were put on the land every alternate year; whereas in the years in which ammoniacal salts were applied alternately one year and mineral matters the following, a very great increase in the wheat crop was obtained, which was likewise the case when ammoniacal salts were continuously used year after year.

With regard to the relative importance of the various fertilizing matters, it may be stated that ammonia or nitrates unquestionably are most useful substances, which the intelligent farmer may turn into profitable account, and the unreasoning one often abuses in a high degree.

But as the atmosphere as well as the rain invariably contain both ammonia and nitric acid, and as all cultivated soils contain both ready-formed ammonia and nitrogenized organic matters, which on gradual decomposition furnish ammonia or nitric acid, or both, the application to the soil of nitrates or ammoniacal salts is not of the same essential primary importance as that of those mineral matters in which the land is deficient. Magnesia, lime, silica, sulphuric acid, chloride of sodium, and even potash, are either present in most soils in great abundance, or if deficient in particular soils, may be economically incorporated with them in the shape of marl, burnt clay, or gypsum, by the consumption of purchased food on the land. All these mineral matters have much less value than phosphoric acid, which is but sparingly distributed in most soils, and is largely required by all plants. Accordingly the removal of phosphoric acid from the land leads more rapidly to partial exhaustion, especially of naturally poor soils, than the removal of any other ash-constituent. Fortunately modern science and commercial enterprise have brought to light the fact, that large deposits of phosphatic materials occur far more abundantly in various parts of the world, than was supposed not many years ago.

[Of the phosphatic materials actually used in England for the manufacture of artificial manures, the following were exhibited:—South American bone-ash; Cambridgeshire and Suffolk coprolites; apatite from Norway; phosphorite from Estremadura; Sombrero, or rock guano, and phosphatic crusts, from Monk's Island, Jarvis Island, Baker Island, and various other small islets in the Caribbæan Sea.]

Should the supply of Peruvian guano come to an end, which it will before many years, English agriculturists will still continue to reap the benefits which commercial enterprize, manufacturing skill and capital, more extended agricultural knowledge, steam-power applied to the cultivation of the land, intelligent labour and applied science have already conferred upon this highly-favoured country.

Conclusive proofs can be given, showing that so far from being in a progressive state of exhaustion, the productiveness of the soils of England has wonderfully increased during the last fifty years; and that the deplorable but hitherto unavoidable loss which the sanitary laws of a civilized country necessitate, is perfectly insignificant in comparison with the immense amount of mineral riches in the great majority of soils, and with the abundant restoration of fertilizing matters to naturally poor land.

The first street locomotive seen in Berlin made, on Monday week, its second journey to Trepton. It is of about 9-horse power, and draws two large passenger carriages. The machine, which cost £600, is built on the system of Aveling and Porter, and promises to turn out a success.

LINDEMANN'S BRICK MACHINERY.

FIG. 1.

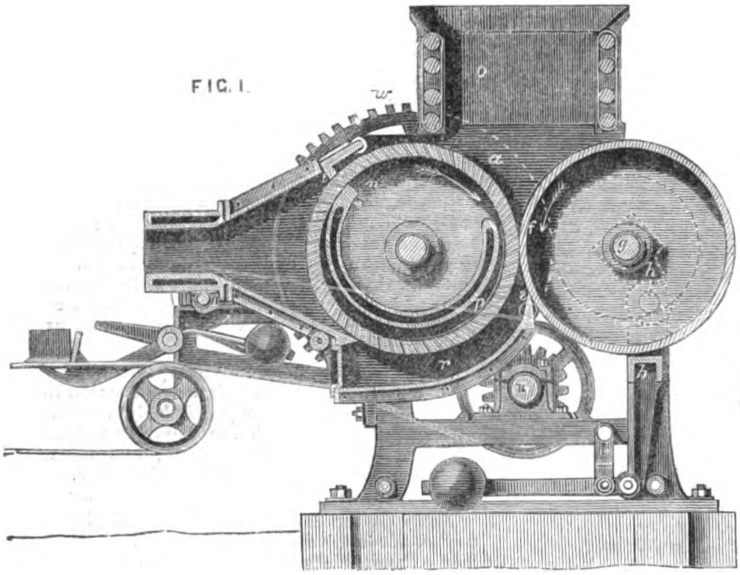

FIG 2.

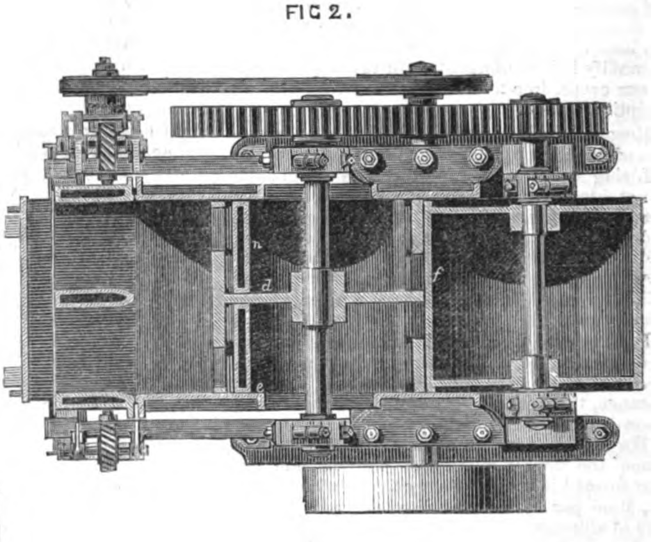

LINDEMANN'S BRICK MACHINERY.

The annexed engravings represent a machine for making bricks, tiles, or other articles, recently patented by Mr. G. Lindemann, of Salford. The invention consists in forcing the plastic material through slits or other openings formed around the periphery of a cylinder, and through which it is again propelled so as to be delivered to any convenient receptacle or at once into moulds. When the articles are formed by being forced through moulds and then cut off, they are caused to abut against a surface retained by levers, which, when the material has been severed, turn downward, and deposit the moulded article on to a travelling apron or other such apparatus.

Another part of the invention relates to the construction of hoppers for delivering plastic materials to rollers or other apparatus which are to operate upon it, and consists in forming the sides of such hoppers of travelling surfaces.

Fig. 1 is a longitudinal section, and Fig. 2 a plan view in section. *a* is a cylinder mounted upon a shaft *b*, and provided with a number of slits upon its periphery. These slits are in four rows, two of them being situate on each side of a disc, which constitutes the connection between the cylinder and its shaft *b*. The cylinder *a* is without ends, and runs against the framing *e* of the machine. In contact with its periphery is another cylinder *f*, mounted upon a shaft *g*, which is carried by a lever *h*, capable of turning upon a fixed centre at *i*. The lower end of this lever is connected by a link to a bell-crank lever *l*, mounted upon a centre and carrying upon its longer arm a weight; by this weight therefore the cylinder *f* is caused to bear against the periphery of the perforated cylinder *a*. At *n* is a curved plate formed in two parts, one on each side of the disc, and situate therefore within the cylinder *a*. This curved surface is fastened at each end to the stationary framework, and does not therefore revolve with the cylinder. The operation of this part of the invention is as follows:—The clay or other plastic material is placed in a hopper *o*, and it falls therefore be tween the two cylinders *a*, *f*, which are caused to revolve in the direction of the arrows. The material being pressed against the cylinder *a* by the cylinder *f*, is forced through the slits in the former, which as it continues so revolve, conveys it downward into the space *p*; and as this space narrows from the bottom towards the upper end, and as the material cannot otherwise escape, it is again caused to pass through the rows of slits in an uniform plastic condition, free from stones or other such matters, and it may thus be received into any convenient receptacle to be subsequently moulded by any ordinary process. The plate *n* is hollow, for the admission of steam if desired. During the operation above described, any stones which would cause an obstruction act upon the cylinder *f* so as to cause it to overcome the weight, and the said cylinder will then turn bodily upon its centre of motion *i*, and allow the stones to fall downward into a receptacle *r*, from whence they may be removed through a doorway. *s* is a scraper for keeping the surface of the cylinder *f* clean, and *t* is another scraper acting after the same manner upon the cylinder *a*. The main driving shaft *u* has upon it a pinion taking into a wheel *w* upon the axis of the cylinder *a*, which wheel gears into another mounted upon the shaft of the cylinder *f*. The moulding of the material is effected in the following manner:—A mould or die is fitted to the front of the machine, and as the material passes through the slits from the inside of the cylinder it is forced forward into the die; as the material passes through the die it is cut off and transferred to an endless apron or belt by means of weighted levers, as clearly indicated in the engraving. As the apron moves onward the moulded article is carried with it, and the weighted lever raises a kind of box to receive another brick to be transferred to the apron as before.

SPENCE'S NON-CONDUCTING COMPOSITIONS.

Mr. J. Spence, of H.M. Dockyard, Portsmouth, has patented an improved composition for preventing the radiation or transmission of heat.

Instead of employing felt and wood lagging with sheet lead covering or other additions as a covering for steam boilers, cylinders, pipes, and such like, for preventing radiation therefrom, or the transmission or passage inward or outward of heat or cold, the patentee applies a composition consisting of the following materials, or the chemical equivalents for the same, combined in or about the proportions herein stated, according to the purpose or the character of the vessel or body for which the coating or covering is intended.

In these non-conducting compositions argillaceous earth is ground and beaten up, and mixed with water so as to form a paste. To the paste is added oil cake, fish or train oil, cow hair, and carbonaceous matter, for giving consistency, and character, or colour according to the purpose for which the composition is required. The hair is well opened and beatened in or incorporated, and the whole is mixed and compounded until it has obtained the requisite degree of density or consistency.

For coating steam boilers and such like vessels subject to great heat, and for other similar purposes, the patentee takes 1,000 lb. in weight of argillaceous earth, and grinds or beats it up and mixes it with water, and so forms a paste; to this is added about 24 lb. of oil cake, about 3 gallons of fish or train oil, and about 24 lb. of cow hair, 24 lb. of soot, and 3 lb. of bone dust or bone ash; these are thoroughly combined together, and form a plaster or composition capable of being applied in the manner of plastering walls and other surfaces.

For coating steam pipes or steam-engine cylinders, and other such bodies and surfaces, the composition is composed of 1,000 lb. of argillaceous earth, prepared as before, and added to this about 30 lb. of oil cake, 2 gallons of fish oil, about 36 lb. of cow hair, 14 lb. of soot, 18 lb. of bone dust, and 14 lb. of ground carbonaceous matter; these are well-incorporated in a finely-divided condition, as before stated. For purposes where a finer quality of coating is required, there may be less oil, less cow hair, and dry matter introduced in proportion to the weight of clay.

For a finishing coat to the previously described compositions, the following composition may be made:—To each 1,000lb. of argillaceous earth, about 1½ or 2 gallons of fish oil, about 32 lb. of cow hair, about ½ gallon of linseed oil, 24 lb. of ground charcoal, and about 8 lb. of glue, to these may be added 8 lb. of paint or colouring matter of any colour or tint which may be preferred.

Steam boilers may be coated whilst in use, and the composition may be applied by hand or trowel, to a depth of ¾ in. or so, and scored or grained across, and allowed to dry, and then a second or any additional number of coatings may be added.

For coating circular pipes, or such like surfaces, a layer of small hay or straw bands saturated in the composition (or any other convenient material) may be lapped or coiled around the pipe or vessel, and the composition plastered on and the coatings or layers added at intervals. Wood laths may be introduced, and any of the well-known means of bonding or binding may be employed, according to the form of the body to which the composition is to be applied, and according to the nature of the action to which the material is to be subjected.

AMERICAN IRON-CLADS.

The *Scientific American* says:—The 11-inch turrets of the "Roanoke" are to be clothed with three additional inches of iron in (as we are informed) solid plates. A space is left between the original turret and the addition thereto, which is to be filled with some fibrous substance; the particular value of the last feature is not apparent. The "Roanoke's" sides are clad with 4½ in. iron on

TURNBULL'S MILLS FOR GRINDING GRAIN.

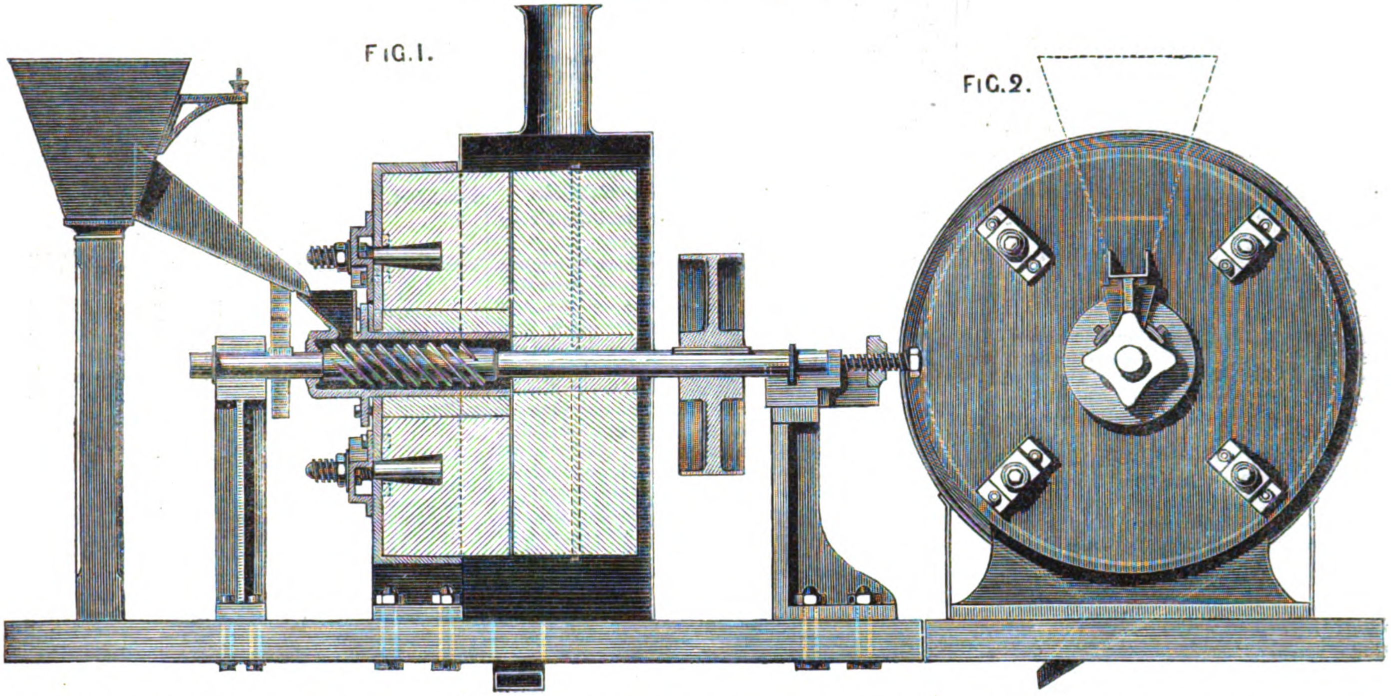

FIG. 1.

FIG. 2.

the old hull; whether this thickness of iron is sufficient to be comparatively invulnerable is extremely questionable. The query suggests itself that if 11 in. of iron, disposed in the strongest manner to resist assault, are insufficient, what will become of 4½ in. of iron on plain snrfaces? The "Mound City," so says the *Telegraph*, received a shot through her 2½ in. solid plating which passed through both sides of the vessel, in all 5 in. of iron. We do not learn that any change is to be made in her construction.

The "Onondaga," at Greenpoint, N.Y., the battery built by Mr. Rowland for the contractor, Mr. George Quintard, of the Morgan Iron Works, is undergoing very important changes in her plan and construction. This vessel had an armament of 4½ in. iron plates fastened directly to an iron hull without wooden backing of any kind. It is now intended to place 12 in. of wood over the 4½ in. plating, and to line this wood on the outboard side with a plate 1 in. thick. The wood will be of oak; 9 in. of it will be laid with the grain at right angles with the ship's length, and the additional 3 in. will consist of planking. The turrets ("Monitor" plan) are also undegoing a change, so we are informed; as it is thought that these improvements will add materially to the effectiveness of the ship. No through bolts will be used in fastening on the wooden facing of the "Onondaga," but the armour will be suspended, as it were, from the deck. This plan has also been recommended for the turrets of the "Monitor" batteries.

It is also said that a partial revolution has been effected in the Ordnance Bureau of the Navy Department, in consequence of the failure of the attack on Charleston, and new instructions have been issued respecting the armament of the ironclads, not only of those at Port Royal but of those now building, and also respecting naval ordnance generally. "The Dahlgren guns are to be removed and an entirely new style of 13-in. gun, using 75 lb. of powder at a load, is to be substituted; this is to be done before the attack on Charleston is renewed. Fort Sumter may be effectively bombarded at a much greater distance by the new guns than by those of the Dahlgren pattern. The new guns are now in process of construction, but it is believed several weeks will elapse before they can be put into a sufficient number of 'Monitors' to permit a renewal of the attack on Charleston."

TURNBULL'S MILLS FOR GRINDING GRAIN.

The annexed engraving shows in sectional view a mill for grinding corn or other grain recently patented by Mr. J. Turnbull, of Barnard's Castle, Durham.

The invention relates to that class of mills for grinding grain known as vertical mills, that is to say, the bed or stationary stone is placed on its edge, and the grinding surface therefore in a vertical position; while the running stone is mounted on a horizontal axis, its face being brought up parallel to the face of the bed stone. The bed stone is placed to about half its thickness into a cast-iron box or case which encircles and fits it somewhat closely, and bolts fixed with lead in the stone project through the holes in the disc of the case, over which are mounted bridge pieces fixed on the case; the screw parts of the bolts pass freely through these bridge pieces and are held by nuts on each side of such bridge frames, by which means the position of the bed stone can be adjusted at will. The shaft on which the running stone is mounted passes quite through the bed stone, and is supported at that end by a bearing formed in a cast-iron boss, fitted in the eye of the stone. The boss fitted in the eye of the bed stone is cylindrical, and considerably larger than the shaft which occupies the centre, in order to receive an archimedian screw which carries the feed through the bed stone, and up to the face of the running stone. The screw is fixed on the shaft, and therefore rotates with it. The feed is delivered by a spout into a small hopper or shoot made on the back end of the boss which conducts it to that end of the screw. The cylindrical boss is bolted to the case receiving the bed stone. The hopper receiving the grain in bulk is in suitable position and has a slide to regulate the passage of the grain, which passes from thence by a spout or shoot to the boss hopper before mentioned; this shoot is fitted with a spring bottom, formed of a sheet of metal, by which the upper end is attached, it is suspended towards the other end by a rod furnished with a regulating screw and nut. Immediately below the shoot bottom is a tappet piece which projects through the stone boss as before mentioned. The tappet has two, three, or more points of contact which strike the bottom of the shoot and cause the grain to pass regularly down the shoot, whereby a regular supply of grain to the stone is insured. In order to regulate the feed, and cause it to supply more or less, the regulating screw may be raised or lowered, and so cause the tappets to strike the bottom with greater or less force. The stones are enclosed in a casing, and air vents provided as usual. The bearing on which the end of the shaft rests next to the running stone is fitted with a sliding brass, against which a screw takes, whereby it, and conseqnently the shaft and running stone, can be forced and kept up to the bed stone at a regulated distance. This journal of the shaft is furnished with one or more projecting rings, fitting into grooves in the brass, the end of which further has a raised part bearing against the end of the shaft, these together take the thrust of the screw; the standards of the shaft bearings, and also the frame of the bed stone, are mounted on a suitable foundation or flooring to keep them in proper relative position.

ON SCIENTIFIC EXPERIMENTS IN BALLOONS.

By James Glaisher, Esq., F.R.S.*

In the introductory part of the discourse, Mr. Glaisher gave a brief history of aërostation, from the discovery of the fire-balloon in the year 1782, by the two brothers Montgolfier, noticing some of the principal ascents made with fire-balloons. He then spoke of the discovery of Cavendish in 1776, viz., that hydrogen gas was fully ten times lighter than common air; when it immediately occurred to Dr. Black, of Edinburgh, that if so, a thin bladder filled with this gas ought to rise of itself; yet a period of several years elapsed before this obvious property was applied to the inflation of balloons; not, in fact, till the success of the fire-balloon was established. He then spoke of the more remarkable ascents and experiments which were made with air-balloons within a few years of its discovery, and remarked, that the result of the several experiments having proved that the balloon would raise great weights in the air, and remain for a long time thus suspended, caused a general desire to navigate the lofty regions of theatmosphere, and to pursue meteorological and other investigations in those regions, and the invention of the balloon was looked upon as likely to be followed by great consequences. He then spoke of the different ascents which have been made in the interests of science: the first of which was that of Mr. Boulton, well known as the partner of the famous Watt, who constructed a balloon to which a match and serpent were attached, that the gas might explode in the air. The object was to determine whether the reverberating sound of thunder was caused by echo or by successive explosions; the point remained unsettled owing to the shouting of the people; but it was thought that the sound did resemble thunder.

---

* Read before the Royal Institution, Col. P. J. Yorke, F.R.S., in the chair.

This experiment was made on December 26, 1784. No further experiments were made, so far as he knew, till the beginning of the present century, when in the years 1803 and 1804, Mr. Robertson made three ascents from St. Petersburg, for the purpose of making magnetical and other experiments.

On August 23, 1804, MM. Gay-Lussac and Biot ascended from Paris for a similar purpose; they attained an altitude of 13,000 feet, and found no difference in their experiments in electricity, magnetism, and galvanism from those made on the earth.

On September 15, Gay-Lussac ascended alone to a height of 22,977 feet; he found that the temperature declined from 82 deg. to 15 deg.; that the sky was deep blue; that the time of horizontal vibration of a magnet was shorter with elevation.

In 1806, Carlo Brioschi, Astronomer-Royal at Naples, endeavoured to ascend higher than Gay-Lussac; the balloon burst, but its remnant happily checked the rapidity of the descent.

A period of forty-four years followed, during which no systematic attempts were made to take scientific observations by means of balloons.

In 1850, MM. Bixio and Barral inflated a balloon with hydrogen gas, in the gardens of the Observatory at Paris, with the intention of ascending to a height of from 30,000 to 40,000 feet; in their first ascent they ascended to a height of 19,000 feet, and descended to the earth in 47 minutes; they passed through a mass of cloud 9,000 feet in thickness.

In their second ascent, clouds were reached at 7,000 or 8,000 feet, which proved to be 15,000 feet in thickness; they never, in fact, passed out of the clouds; for when they were 23,000 feet high, they began to descend, owing to a rent in the balloon.

Mr. Welsh's experiments were made in the year 1852: on August 17 and 26, October 21, and November 10, the respective heights attained in these were 19,500 feet, 19,100 feet, 12,640 feet, and 22,930 feet: a great number of observations were made, from which the following law regarding the decline of temperature with elevation was deduced:—

> "That the temperature of the air decreases uniformly with the height above the earth's surface, until at a certain elevation, varying on different days, the decrease is arrested, and for a space of 2,000 or 3,000 feet the temperature remains nearly constant, or even increases by a small amount; the regular diminution being afterwards resumed and generally maintained at a rate slightly less rapid than in the lower part of the atmosphere, and commencing from a higher temperature than would have existed but for the interruption noticed."

These results, as well as those found by Gay-Lussac relative to the decline of temperature with increase of elevation, appeared to confirm the law which theory, based upon observations upon mountain sides, assigns for the gradation of temperature, viz., a decrease of one degree of temperature for every increase of 300 feet. Up to the present time, therefore, the high expectations entertained on the discovery of the balloon have never been realized.

The speaker then proceeded to state, that since the formation of the British Association, grants of money have been made for the purpose of pursuing these inquiries; but with the exception of those by Mr. Welsh, none have been made.

In the year 1861, another grant of money was made, and a committee appointed to carry out experiments by means of the balloon, and the task of making these experiments was undertaken by the speaker.

The primary objects of the experiments with which he was entrusted were:—

The determination of the temperature of the air and its hygrometrical states at different elevations up to five miles.

To compare the readings of an aneroid barometer with those of a mercurial barometer up to five miles.

To determine the electrical state of the air.

To determine the oxygenic state of the air by means of ozone papers.

To determine the time of vibration of a magnet on the earth, and at different distances from it.

To determine the temperature of the dew point by Daniell's Dew Point Hygrometer, Regnault's Condensing Hygrometer, and by the use of the Dry and Wet Bulb Thermometers as ordinarily used, and by their use when under the influence of the aspirator, so that considerable volumes of air are made to pass over their bulbs, at different elevations, as high as possible, but particularly up to those heights where man may be resident or where troops may be located, as in the high lands and plains of India, with the view of ascertaining what confidence may be placed in the use of the Dry and Wet Bulb Thermometers, by comparison with the results as found from them and with those found directly by Daniell's and Regnault's Hygrometers; and to compare the results as found from the two hygrometers together.

To collect air at different elevations.

To note the height and kind of clouds, their density and thickness at different elevations.

To determine the rate and directions of different currents in the atmosphere.

To make observations on sound.

To note atmospherical phenomena in general, and to make general observations.

The speaker then described the method of managing a balloon, spoke briefly of the several ascents already made, and then proceeded to speak of some of the results.

Speaking of the ascent on July 17, the departure of the temperature from a regular progression was very remarkable. Below the cloud the decrease was nearly uniform; on passing above it there was an increase of 6 deg.; the decrease was then resumed, and the temperature was 26 deg. at 10,000 ft. and continued at this reading till 13,000 ft. had been passed; a very remarkable increase then took place, and at 19,500 ft. a temperature of 42 deg. was registered, and then declined rapidly to 16 deg. at five miles. In descending, a disturbance from a regular increase was met with at 24,000 feet, and continued to 17,000 feet; at 13,000 feet clouds were reached, and no observations were made below 10,000 feet.

The temperature of the dew point approached that of the air in the cloud, but did not touch it, and then separated more and more until at the highest point there was almost an entire absence of moisture.

On August 18, the temperature of the air decreased as usual on leaving the ground, until at the height of 4,000 feet the rapidity of the decrease was checked, and a warm current of air was met with and continued to 11,500 feet; the balloon then descended and passed through the same warm current extending to the same limits, and again passed through it on its reascension at about the same height, and extending to 14,000 feet, when the regular diminution was resumed and continued to the highest point; on descending, the same warm current was met with, and continued till the clouds were entered at 6,500 feet, which caused another interruption in the regular increase of temperature as is usual on entering cloud.

In the ascent on September 5, on passing out of the cloud there was an increase of temperature of 9 deg.; and then no interruption was met with till a height of 15,500 feet was reached, when a warm current of air was reached, and continued to 24,000 feet: then a regular decrease was experienced till the highest point was reached. On descending, the same warm current was encountered between 22,000 and 23,000 feet; and a similar interruption, but to a greater amount, was experienced till the balloon had descended to about the same height as it was first met with on ascending. After this there was no further interruption till the descent was completed. A table was then formed from all the observations, showing the decrease of temperature for successive increases of elevation of 1,000 feet. The results are as follows:—

When the Sky was Cloudy.

	Ft.		Ft.		Deg.				Deg.		Ft.
From	0	to	1000	was	4·7	from	7	experiments, or	1	in	213
,,	1000	to	2000	was	4·2	from	7	,,	1	in	239
,,	2000	to	3000	was	4·1	from	10	,,	1	in	244
,,	3000	to	4000	was	3·7	from	10	,,	1	in	271
,,	4000	to	5000	was	3·1	from	6	,,	1	in	323

From these results it will be seen that when the sky is cloudy, the decline of temperature differs very little from the theory of a decline of temperature of 1 deg. in 300 feet.

But When the Sky is partially Clear.

	Ft.		Ft.		Deg.				Deg.		Ft.
From	0	to	1000	was	7·2	from	5	experiments, or	1	in	139
,,	1000	to	2000	was	5·3	from	5	,,	1	in	189
,,	2000	to	3000	was	4·6	from	5	,,	1	in	254
,,	3000	to	4000	was	3·4	from	6	,,	1	in	295
,,	4000	to	5000	was	2·7	from	7	,,	1	in	370

These results differ considerably from those formed in a cloudy sky, and doubtless the difference between experiments carried on under a cloudless sky would differ still more. They do not at all confirm the theory of a decline of 1 deg. of temperature in 300 feet.

The Decrease of the Temperature of the Air, at heights exceeding 5000 feet.

	Ft.		Ft.		Deg.						Ft.
From	5,000	to	6,000	was	2·8	from	10	exprimts., or	1	in	357
,,	6,000	,,	7,000	,,	2·8	,,	8	,,	1	,,	357
,,	7,000	,,	8,000	,,	2·7	,,	8	,,	1	,,	370
,,	8,000	,,	9,000	,,	2·6	,,	8	,,	1	,,	384
,,	9,000	,,	10,000	,,	2·6	,,	8	,,	1	,,	384
,,	10,000	,,	11,000	,,	2·6	,,	8	,,	1	,,	384
,,	11,000	,,	12,000	,,	2·6	,,	6	,,	1	,,	384
,,	12,000	,,	13,000	,,	2·5	,,	6	,,	1	,,	400
,,	13,000	,,	14,000	,,	2·2	,,	6	,,	1	,,	455
,,	14,000	,,	15,000	,,	2·1	,,	9	,,	1	,,	477
,,	15,000	,,	16,000	,,	2·1	,,	9	,,	1	,,	477
,,	16,000	,,	17,000	,,	1·9	,,	9	,,	1	,,	527
,,	17,000	,,	18,000	,,	1·8	,,	9	,,	1	,,	556
,,	18,000	,,	19,000	,,	1·8	,,	9	,,	1	,,	556
,,	19,000	,,	20,000	,,	1·5	,,	9	,,	1	,,	667
,,	20,000	,,	21,000	,,	1·3	,,	9	,,	1	,,	771
,,	21,000	,,	22,000	,,	1·3	,,	9	,,	1	,,	771
,,	22,000	,,	23,000	,,	1·0	,,	9	,,	1	,,	1,000
,,	23,000	,,	24,000	,,	1·3	,,	2	,,	1	,,	771
,,	24,000	,,	25,000	,,	1·1	,,	2	,,	1	,,	909
,,	25,000	,,	26,000	,,	1·0	,,	1	,,	1	,,	1,000
,,	26,000	,,	27,000	,,	1·0	,,	1	,,	1	,,	1,000
,,	27,000	,,	28,000	,,	0·9	,,	1	,,	1	,,	1,012
,,	28,000	,,	29,000	,,	0·8	,,	1	,,	1	,,	1,050

These results follow almost in sequence with those found with a partially clear sky; and together show that a change takes place of 1 deg. of temperature in 139 feet near the earth, and only in 1,000 feet at the height of 30,000 feet, and plainly indicates that the decline of 1 deg. of temperature must be abandoned.

Treating the observations for determining the degrees of humidity of the air in the same way, the following are the results:—

When the Sky was cloudy, saturation being considered as 100,

On the earth the degree of humidity was			78	from	5	expts
At height of	1,000	the degree of humidity was	76	,,	9	,,
,,	2,000	,,	77	,,	11	,,
,,	3,000	,,	75	,,	11	,,
,,	4,000	,,	80	,,	10	,,
,,	5,000	,,	81	,,	5	,,
,,	6,000	,,	82	,,	3	,,

The law of moisture here shown is an almost uniform state of humidity to the height of 3,000 feet, viz., 76·5; then a decrease on the next 1,000 feet, and an increase to 83 and 82 at 5,000 and 6,000 feet.

When the Sky was partially Cloudy,

On the ground the deg. of humidity was			63	from	4	expts
At height of	1,000	the deg. of humidity was	68	,,	5	,,
,,	2,000	,,	77	,,	5	,,
,,	3,000	,,	76	,,	5	,,
,,	4,000	,,	76	,,	7	,,
,,	5,000	,,	69	,,	6	,,
,,	6,000	,,	68	,,	6	,,

At heights exceeding 6,000 feet, the following were the results:—

	Ft.					
At height of	7,000	the deg. of humidity was	64	from	7	expts
,,	8,000	,,	58	,,	7	,,
,,	9,000	,,	52	,,	7	,,
,,	10,000	,,	82	,,	7	,,
,,	11,000	,,	48	,,	5	,,
,,	12,000	,,	48	,,	8	,,
,,	13,000	,,	43	,,	5	,,
,,	14,000	,,	58	,,	2	,,
,,	15,000	,,	53	,,	3	,,
,,	16,000	,,	45	,,	3	,,
,,	17,000	,,	33	,,	3	,,
,,	18,000	,,	21	,,	2	,,
,,	19,000	,,	36	,,	2	,,
,,	20,000	,,	33	,,	1	,,
,,	21,000	,,	12	,,	1	,,
,,	22,000	,,	31	,,	1	,,
,,	23,000	,,	16	,,	1	,,

The laws of moisture here indicate a humidity near the ground less by 15 with a partially clear sky, than in a cloudy sky; starting with 63 in the former state on the ground, increasing to 77 at 3,000 ft. high; then nearly constant to 5,000 ft., when it abruptly decreased to 69 and 68 at 5,000 and 6,000 ft., and then decreased nearly evenly at the rate of 5 in 1,000 ft., till at 9,000 ft. and 10,000 it was 52; the degree then constantly decreased till at a height exceeding 25,000 ft. it was less than 10, and it would seem that at higher elevations there was an almost entire absence of water. These seem to be the general laws; but this regular diminution is evidently often interrupted, and strata of moist air may exist, or be passing at different elevations, even up to 20,000 ft., of some thickness.

Electrical State of the Air.—In the ascent on July 17, the air was found to be charged with positive electricity, becoming less in amount with increased elevation, till at the height of 23,000 ft. the amount was too small for observation. The instrument was broken in the descent, and was not afterwards used.

Time of Vibration of a Magnet.—The general result of all the experiments is, that the magnet vibrates in a *somewhat longer interval* of time at higher elevations than on the earth. The result is contrary to that found by Guy-Lussac in 1804.

On the Propagation of Sound.—From observation made in the different ascents, it was learnt that different notes and sounds pass more readily through the air than others: for instance, the barking of a dog and the whistle of a railway engine have been heard at a height of more than two miles, whilst the shouting of several thousand people cannot be heard at the height of one mile.

On the Oxygenic Condition of the Atmosphere.—On July 17, the test papers by Moffat and Shönbein, were untinged by colour throughout the journey; and the same result was found during the ascent on July 30.

On August 10, Mr. Glaisher received a letter from Dr. Moffat, of Hawarden, expressing surprise at this result, inasmuch as it has always been received as a theory, that ozone increases in quantity with increased elevation.

In consequence of this, Mr. Glaisher went to Dr. Moffat, at Hawarden, and requested him to make some papers, which he did, and these papers were used on August 18, together with some prepared by Messrs. Negretti and Zambra, and some prepared according to Schönbein's formula; and at 22,000 ft. the colouration was 4 on a scale whose deepest tinge is 10, whilst those prepared by Schönbein were coloured to 1 on the scale, and those by Negretti and Zambra, were uncoloured; in consequence of this, the preparation of the papers by Messrs. Negretti and Zambra has been stopped.

Physiological Observations.—On July 17, before starting, the number of Mr. Coxwell's pulsations were taken, and found to be 74 in one minute; and Mr. Glaisher's were 76 in one minute.

At a height of 17,000 ft., Mr. Glaisher's had increased to 100, and Mr. Coxwell's to 84; and on reaching the ground, the number was 76 with both gentlemen.

On August 21, no observations were taken before starting. At the height of 1,000 ft., the following results were obtained:—

Mr. Coxwell	96	per minute.
Mr. Ingelow	80	,,
Capt. Percival	90	,,

At 11,000 feet—

Mr. Coxwell	90	in a minute.
Mr. Ingelow	100	,,
Capt. Percival	68	,,
Mr. Glaisher	88	,,
Master Glaisher	89	,,

At 14,000 feet—

Mr. Coxwell	94	per minute.
Mr. Glaisher	98	,,
Mr. Ingelow	112	,,
Capt. Percival	78	,,
Master Glaisher	89	,,

The pulsations of Capt. Percival were so weak that he could scarcely count them; whilst those of Mr. Coxwell he considers had increased in strength.

From these results it will be seen that diminished pressure exercises a different influence upon different individuals.

On July 17, at 19,000 ft. the hands and lips were noted as being dark-blue, not the face. At the height of four miles the palpitations of the heart were audible, and the breathing was affected.

On August 18, the hands and the face were blue at the height of 23,000 ft.

On September 5, at the height of about 29,000 ft. Mr. Glaisher became unconsious, and at 53,000 ft. Mr. Coxwell lost the use of his hands. At 29,000 ft. on descending, Mr. Glaisher began to recover, and at 25,000 ft. the observations were resumed.

The general results of these eight ascents are:—

1st. That the temperature of the air does not decrease uniformly with the height above the earth's surface, and consequently the theory of a decrease of 1 deg. of temperature for an increase of elevation of 300 ft. must be abandoned. In fact, more than 1 deg. declined in the first hundred feet when the sky was clear, and not so much as 1 deg. in 1,000 ft. a height exceeding 5 miles.

These experiments are the first to yeild any definite information on the subject; more experiments are required to settle the law satisfactorily, but its effect on the laws of refraction will be great: all the elevations of the balloon are to a certain extent erroneous, for it has never happened that the mean of the extremities has given the mean of the whole column of air.

2nd. The degree of humidity decreased wonderfully with the height, till at above 5 miles there was scarcely any aqueous vapour at all.

3rd. That an aneroid barometer can be made to read correctly, to the first place of decimals certainly, and to the second place of decimals probably, to a pressure as low as 7 inches.

4th. That a dry and wet bulb thermometer can be used effectively up to any height on the earth's surface where man may be located.

5th. That the balloon does afford a means of solving with advantage many delicate questions in physics.

J. G.

PRACTICAL HINTS FOR THE CONSTRUCTION OF LIGHTNING CONDUCTORS.

By M. Sacre.

Beginning at the upper end of the lightning conductor we have first the platina point; it generally suffices to be made 1½ in. high and ⅜ in. diameter at its base; the base of the copper cone 11-16ths in., while the iron rod is ¾ in. diameter, copper being a better conductor than iron. It is preferable to make the rod of round, rather than of square iron. The rod should increase in diameter downwards, and should consist of 6 ft. lengths, each welded together—these lengths are screwed together with 1 in. gas thread sockets. If the ground string of the conductor is to be led overground, it ought to be 11-16ths of an inch, if underground, ¾ of an inch diameter, in either case to be made of bar iron and not wire cable. The copper cone is 11-16ths of an inch diameter screwed and 1½ in. long; the iron rod adjoining is screwed similarly; but one must have a left and the other a right handed thread, joined by a corresponding screwed socket, the end of the rods abutting against each other. All the other joints to be made in the same way. The horizontal string of the conductor joined to the vertical by hard-soldering a ring welded on to the former to the latter. The ground string terminates in a cast-iron pipe filled with charcoal, and with a hermetically closed cover, screwed at the part where the conductor passes through. The end of the conductor is screwed into a metallic disc. If it is led into a well, the disc should be of cast-iron of from 6½ to 8½ sq. ft. area, resting on the bottom of the well.

If it ends in the earth, however, the end should be of a copper cylinder, of 10 to 20 sq. ft. superficial area, according to the moisture in the soil. The diffusion of the current is more effective, the larger the surface. If the ground string is made of wire cable, the end of the same should be soft soldered into a piece of iron, whose other end is screwed. A screwed socket joins the same to the ring, or other part of the conductor. The mode of joining by screwed sockets is simple and cheap and is very convenient in laying the ground string of the conductor when made of round bar iron, as recomended.—*Practical Mechanics' Journal.*

OPENING OF THE BHORE GHAUT RAILWAY INCLINE.

Such events as the celebration of the opening of the Bhore Ghaut Incline of the Great Indian Railway, present a refreshing contrast with the sad records of daily intestine strife which Indian papers but too lately presented. We hail the increased development of railway communication in our Indian dependencies as an assurance of peace and tranquillity not likely to be easily disturbed. The active part taken by the Government in the promotion of this line goes far to prove, that England at least understands that the civilization of India should be one of her first objects. Little doubt remains that to her we may in future look for the greater proportion of our cotton supply; and the success which has attended the working of the heavy inclines on this line proves, plainly enough, that there will be no difficulty whatever in supplying a means of transit by which the precious material may easily be brought to convenient shipping ports. The *Bombay Saturday Review* says:—

"The Incline reaches at one long lift the height of 1,832 ft., the highest elevation yet attained by any railway incline. It is 15¼ miles long, and its average gradient consequently 1 in 46·39. The highest gradient is 1 in 37, and the sharpest curve 15 chains radius. The tunnels are 25 in number, the greatest length of any of them being 341¼ yards. There are eight viaducts, one consisting of eight arches of 50 ft., and being 129 ft. high, and another of a like number of arches with a maximum height of 143 ft. The quantity of cutting amounts to 2,067,738 cubic yards, and of embankments to 2,452,308 cubic yards; and there are 22 bridges of various spans, and 74 culverts. The total cost of the works has been £1,000,000, or £68,750 a mile.

"The Giovi Incline is upon the Turin and Genoa Railway, and commences 7¼ miles from Genoa, a point 295 ft. above the level of the Mediterranean, and ascends the Appenines. The Semmering Incline is upon the Vienna and Trieste Railway, and crosses the Noric Alps at the pass of that name. It is replete with extensive and extraordinary works. The preliminary operations and study of this Incline occupied from 1842 to 1848, a period of six years. It was opened in May 1854, its construction having taken 5¼ years. Upon the Bhore Ghaut, about four years were spent in preliminaries, and the works have been completed in about 7¼ years from the date of their commencement. In the four months of the monsoon, during which about 150 in. of rain fell, no work could be carried on except in some of the tunnels, where the work has never ceased night or day.

"The fact last mentioned, of the completion of the works in the comparatively short period of 7¼ years, is the more remarkable, because the Incline was for a long time singularly unfortunate in its contractors. Mr. Faviell, whether through his own neglect or through a mistake in the terms of the contract, spent a great deal of money and did very little; Mr. Tredwell died within a fortnight of the time of his arrival in India; and Messrs. Adamson and Clowser had all their exertions defeated by the outbreak of cholera, which destroyed some thousands of their native workmen, and dispersed the rest. Less energetic men would have been disheartened by such a constant succession of misfortunes; but Messrs. Adamson and Clowser only pushed onward with more determined resolution, and success has at last crowned their untiring efforts."

THE SOUTH ESSEX WATERWORKS.

A NUMBER of gentlemen connected with science and art and sanitary interests assembled together on Saturday last at Grays, Essex, to witness the interesting ceremony of the opening of the South Essex Waterworks. The purpose of the Company, of which Mr. Alfred Smee, F.R.S., is the chairman, is, in the first place, to supply the towns and villages of South Essex with water, and subsequently to make the water available for any deficiency that should occur in any part of London.

The chalk pits of Grays, where the works are erected, are situate about a mile from the Thames; they cover an area of nearly 60 acres, and are filled with water springs, which are so prolific, and are perpetually rising in such large volumes, as to produce a million of gallons per day.

The Company have now completed their high-service works, and have laid on the water to Brentwood and Warley; in the course of time an abundant supply of water will be furnished to the towns in the upper part of the county, and ultimately to the eastern suburbs of London. At present five pumps are employed, and the quantity of water obtained every 24 hours is 2,100,000 gallons.

The following is a description of the pumping apparatus, &c., from particulars furnished to us by Messrs. Easton and Amos, the engineers to the works. The steam-engine employed for raising the water from the chalk-pit to the reservoir at Warley, is constructed upon the principle known as Woolf's double cylinder, and is the most economical and convenient agent that can be employed for this purpose. The steam is first used at high-pressure in the small cylinder, where it is allowed to exert its full power throughout the entire stroke; from this it passes into a larger cylinder four times the capacity of the small one, so that it is then expanded to four times its first bulk, and, consequently, its final pressure is reduced in a like proportion; it then passes into the condenser beneath the cylinders, where it is again converted into water, and in this process a vacuum is formed which draws down the piston on the large cylinder, and then the whole power of the steam is made available. The water is raised by a pump, which is worked by a rod direct from the wrought-iron beam of the engine. The pump is double-acting, having both a bucket and plunger, and thus represents a combination of the common lift pump, with a force pump similar to that used for feeding boilers. The bucket is twice the area of the plunger, and the consequence of this is—that it draws at the up stroke the full contents of the barrel, but only discharges one-half into the delivery pipe, the other half being displaced by the plunger at the down stroke. This causes a pretty uniform flow of water, and enables it to be forced, with the assistance of a large air-vessel, straight into the main, without the intervention of a stand-pipe. It is believed that this is the only instance of water being raised to a height of 400 ft. through a main 9¼ miles in length.

With regard to the source of the water, it issues from the chalk formation out of vertical fissures which have been formed by some upheaving of the strata, and which takes one general direction. To obtain water, all that is to be done is to cut across these fissures, each of which is separate from the other.

Owing to the operations which have taken place in working these chalk pits, very little tunnelling is required. The tunnel in use at present is 25 ft. long and 5 ft. broad, and this can be extended to indefinite proportions according to requirement.

The origin of this company was somewhat singular. Mr. Meeson, the owner of the property, having worked out the chalk to the level of the springs, attempted to go deeper, but was stopped by an immense influx of water. Engines were then erected, the power of which was gradually increased until 10,000,000 gallons of water were daily pumped into the Thames. At this point Mr. Meeson advertised for engineering assistance; the advertisement was answered by Messrs. Easton and Amos; and thus in due course, that which originated in accident, has been turned to practical account and for the benefit of the public.

GAS WORKS IN GERMANY.

THERE are in Germany 266 gas works, of which 66 are worked by townships or individuals, and 200 belong to various companies.

The combustible employed is chiefly coal, the largest quantity being supplied from England. Out of 7½ million quintals, 3,350,000 are obtained from the English collieries. Berlin, which produces annually 800 million cubic feet of gas, uses about half of this quantity of coal. Hamburg takes more than 500,000 quintals, and the rest is used in the gas works of Altona, Lubeck, Rostock, Stralsund, Stettin, Dantzic, Konigsberg, &c. The excellent quality of the English coal for gas-making causes the preference to be given to it over indigenous coal; but if the cost of transport of the latter can be cheapened, it is thought that it will ere long come into use in Hamburg, Berlin, and other towns.

The following are the percentage proportions in which the various coal is used in Germany:—

English coal	46.00
Westphalia	18.00
Moravia	11.50
Zwickan	7.50
Saarbuck	7.00
Silesia	5.00
Dresden	2.25
Bohemia	2.00
Northern Bavaria	0.75
	100.

Besides the gas works which consume coal, Germany possesses 20 in which wood alone is employed for distillation; and there are two small works in Holstein which consume peat or turf at certain times, and at others coal.

The retorts used are generally of clay, except in those works where gas is made from wood. The total number of retorts employed is estimated at 7,337, made for the most part in the immediate locality of the works; their form and size differs considerably.

Assuming that the mean consumption of gas in the 24 hours is 25 millions of cubic feet, and supposing that each retort furnishes daily 4,500 cubic feet, it follows that these 7,337 retorts must be continually, or three-fourths of the time, in work.

The use of extractors is much less general than would be supposed. There are only 90, or less than a third of the whole of the gas works in Germany which employ about 107 extractors. The small works do not employ them at all.

The meters in general use are water-meters of native manufacture, and may number about 139,000. The mean number of lights of each is about eight.—*Journal de l'Eclairage au Gaz.*

Miscellanea.

A prospectus has been issued of the Crystal Palace and South London Junction Railway, an extension of the London, Chatham, and Dover line by Peckham to the Crystal Palace. The capital is to be £675,000, in shares of £10, of which one-half are to carry a 6 per cent. preference. The station at the Crystal Palace will be on a level with the floor of the building.

A prospectus has been issued of the Copenhagen Railway Company, with a capital of £160,000, in shares of £10. The object is to carry out some concessions granted by the Government for the construction of lines of railway to be worked by horses only, from the centre of the capital to the most frequented parts of the suburbs. The aggregate length of the lines to be first made is ten miles, at a cost of £4,500 per mile.

We are glad to find that upwards of £300,000 have been subscribed to the Atlantic Telegraph Company. Letters of allotment were issued on Tuesday last by the directors.

The preliminary announcement has been made of a new project, bearing the title of the Cape Race Electric Telegraph and Lightship Company (Limited). It is intended to construct, equip, and station a steam lightship off Cape Race, Newfoundland, in the track of steam and and sailing ships bound to and from the North American Colonies and the northern ports of the United States. The lightship will have telegraphic communication with the shore by means of a submarine cable, one end of which is to be worked on board the vessel. It is urged that by these means there may be obviated throughout one-half of every year an unnecessary delay of three days, which now occurs in the receipt and exchange of news between Europe and America. Various other useful services are to be rendered, with the aid of a steam tender. The capital proposed is £100,000.

Les Mondes says:—A bank-note printed in blue, on a yellow ground, is the only one which photography cannot reproduce with success.

We learn, from experiments conducted at Brest by M. Le Guen, that castings containing a small per centage of wolfram, are far superior to those of the ordinary kind; the principal advantage conferred being increased elasticity.

Dr. Walter Lewis, the medical officer of the London Post-office, states in his report just issued that he has arrived at these conclusions from observations of the health of the travelling officers of the Post-office,—That railway travelling has little, if any, injurious effect on the healthy, strong, well-built persons, if the amount be not excessive and if they take moderate care of themselves; but that persons who take to habitual railway travelling after the age of 25 or 30 are more easily affected than those who begin earlier, and that the more advanced in age a traveller is the more easily is he affected by this sort of locomotion. Weak, tall, loosely-knit persons, and those suffering under various affections, more especially of the head, heart, and lungs, are very unsuited for habitual railway travelling.

In Perth, on Sunday last, a new lamplighting apparatus was used, consisting of a small lamp covered with gauze work, which is attached to the end of a stick of sufficient length to enable the man to turn the stop-cock, and so light the gas. The plan wrought admirably, and a considerable saving of time was effected, even on the first night of trial.

The official Admiralty designs, prepared under the direction of Mr. Reed, for the re-construction of the wooden frigate "Belvidera," 51, as an armour-plated frigate, have been received at Chatham dockyard, and are now being copied to scale, preparatory to the vessel being taken down and re-constructed under No. 7 shed, where preparations are making for commencing the work as soon as a sufficient number of hands are released from the other vessels now in progress. The statement that the "Belvidera" is to be converted into an armour-plated frigate, according to the plans of Mr. Laing, the master-shipbuilder at Chatham, is not strictly correct. Although he prepared designs for the new vessel, they were not acted upon by the Admiralty. The "Belvidera," as well as the whole of the five armour-plated frigates ordered to be built in accordance with the recent decision of the House of Commons, are to be constructed from the designs prepared by Mr. Reed.

A prospectus as been issued of the Photogenic Gas Company for the purpose of introducing the, patent of M. Mongruel, which is alleged to produce either from ordinary gas or from atmospheric air, a light more powerful, cheap, and healthy than any hitherto known. The proposed capital is £200,000 (of which one-half is to be first put forth) in shares of £20. The price to be paid for the patent is £5,000 in cash and £45,000 in shares.

A prospectus has been issued of the Dunaburg and Witepsk Railway, with a capital of £2,600,000 in shares of £100. The length is to be 161 miles, to connect Dunaburg, the terminus of the Riga and Dunaburg line, with Witepsk, and thus bring forward the produce of a rich agricultural district. A contract for its construction has been made with Messrs. Peto and Betts, for a total of £2,143,615, and as the Russian Government guarantee 5 per cent on £2,600,000—namely, £130,000, per annum—while the amount requsite to be called up on the shares will thus be only £33, a revenue of 6 per cent. will be yielded.

A NOVEL STEAMER.—The screw-steamer "Nautilus," Captain Wintringham, which arrived at Hull on Wednesday morning from St. Petersburg, brought a small tubular cigar-shaped steamship, which was built about two years ago by a gentleman named Winan. This novel steamer, which is built on the same principle as the American tubular vessel, drawings of which appeared in the *Illustrated London News* about two years ago, has been brought to this country for the purpose of experimenting upon. She is at present 80 ft. long, and in the widest part amidships is 8 ft. in diameter. We understand, however, that she is to be considerably enlarged, and for that purpose will be handed over to Messrs. Earl and Co., shipbuilders of Hull. The owner is confident that, after she is lengthened, and other improvements made, she could cross the Atlantic with perfect safety, and would answer admirably for an American mail boat. On the top or back of the vessel there are four short tubes projecting about two-and-a-half feet, which will answer the purpose of ventilators, and as a means of entrance to the vessel. To prevent the steamer rolling over in the water, she is well ballasted with spelter, and draws about 3 ft. of water. There are several screws in her sides to which stanchions may be fastened. On this a grating to form a deck is fixed, and an iron guard runs from stem to stern. The vessel is propelled by means of a screw, which is placed about 20 ft. from the stern. She is fitted with a rudder at each end.

The British Navy in 1677.—A correspondent of the *Standard* writes:—I send you a list of all our navy in the year 1677, taken from a manuscript book written for the private use of King Charles II., it being the only record of the navy of that period (see "James' Naval History," vol. I., pp. 8 and 537), which is in my possession.

Novel American Cartridge.—Powder and ball in contact are together made up in an exceedingly thin envelope of india-rubber, which effectually protects the powder from damp; by this means the use of paper is rendered unnecessary, and the time required for loading reduced to the lowest possible limit. It is said that the French Government have taken the adoption of the invention under consideration.

The Log Supeseded.—An experiment has just been made on the Seine, at Paris, with an instrument called a *lochometre*, for measuring the speed of vessels. This instrument, which is intended to supersede the log now in use, is composed of a metal syphon, of which the extremities are immersed in the water. A small screw is fitted to the top and to the interior of the instrument, on which the water acts as soon as the ship or boat moves, by constantly entering one end of the syphon and running out at the other. Some clockwork is attached to the screw, the functions of which are to mark on a dial-plate by hands the distance in yards performed by the vessel, commencing with one unit, and extending to hundreds of miles. The experiment was tried on board the steamboat "Parisien," which carries passengers between Paris and St. Cloud. The distance was accurately marked on the dial-plate by the movement of the hands.

The Anchors and Chain Cables Bill.—At the monthly meeting of the Liverpool Chamber of Commerce on Monday, it was agreed to petition in favour of Mr. Laird's bill for regulating the tests of anchors and chain cables according to the provisions made by the Admiralty.

The Manufacture of Great Guns.—We are waiting anxiously as to some report upon the qualities of the 23-ton 600-pounder. This gun, as our readers may remember, is rifled on a modification of the shunt principle, its elongated projectiles being furnished with buttons, similar to those on one of the 300-pound shot fired against Messrs. Brown's thick plates at Shoeburyness. We are the more anxious to have some report about this 600-pounder, as the endurance of heavy guns firing rifle projectiles with large charges has not been satisfactory; but we believe that Sir William Armstrong is able to fire the round ball also of his modified shunt-rifled piece. Respecting our old acquaintance, the Horsfall gun, we are also desirous to hear something, and trust that its early reappearance at Shoeburyness will put to silence all doubts as to the healthy condition of a very fine forging. The guns now being prepared by the Ordnance Select Committee for the trial of the system of rifling previously described by us are to be built up round steel tubes toughened by immersion in hot oil, on the plan introduced by Mr. Anderson, who, since Sir William Armstrong's resignation, has had the entire direction of the work in the gun factories at Woolwich. This talented and practical mechanic has lately, we understand, submitted a plan for making field-guns in three or four pieces only, which will materially reduce both labour and cost, at the same time that it will greatly increase the endurance of the gun, and render it less liable to damage from the rough usage of war.—*Army and Navy Gazette.*

New Pier, Holyhead.—On Monday, a new stone pier, nearly 500 yards long, extending through the large area under Tan-y-ran from the railway station to the old pier, was commenced. The London and North-Western Railway have contracted with Messrs. J. and C. Rigby, of Royal Victoria Harbour, Holyhead; and we understand that the whole works will cost at least £250,000.

Photolectric Engraving.—Mr. Duncan C. Dallas, of 102, Fleet-street, has invented a process which, though imperfect at present, has considerable and obvious benefits. Mr. Dallas proposes to obtain from a clear photograph an engraving possessing a softness, detail, and a peculiar vigour of its own. Printing ink, which, when really good, is beautiful and free from a greyish colour after years of wear, is to be used for this purpose. We have before us a couple of specimens from Mr. Dallas's process—which have not been touched by the engraver—and which possess a peculiar soft and delicate tone. We shall trace the progress of this new branch of the photographic art with interest, as it bids fair to become of considerable utility.

The International Exhibition Buildings.—A supplementary Civil Service estimate was published on Monday last, showing that a vote of £172,000 is to be asked for the "purchase of land and purchase and alteration of buildings used for the purposes of the late International Exhibition." The following are the particulars of the vote:—

—	Total Estimate for the Service.	Vote Required for 1863-4.	Further Amt that may be Required.
	£	£	£
For the purchase of land and certain buildings from Her Majesty's Commissioners for the Exhibition of 1851 ...	120,000	67,000	53,000
For the purchase of existing Exhibition buildings from the contractors	80,000	80,000	—
For repairing, altering, and eventually completing the building.	284,000	25,000	259,000
Total	484,000	172,000	312,000

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the Mechanics' Magazine at the rate of 6d. per line, or 5½d per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisments.

All communications should be addressed to the Editor, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

Received.—G. S.—G. A. D.—J. A. and Sons.—J. H.—Com. S.—Dr. W.—J. P.—W. W.—Capt. N.—B. Bros.—S. and Co.

Thos. Walker (Birmingham).—The information you refer to was derived, as far as Mr. Hall's engine is concerned, from a statement made in a book edited by Mr. Scott Burn. Professor Rankine obtained nearly similar results from the engine of the "Thetis." Messrs. Rowan or Messrs. Randolf and Elder might possibly supply you with what you require.

D. H.—Two patents were taken out in 1858 for weighing cranes, but we are unable to say if either is the property of the Kirkstall Forge Company. One was granted to E. Moss, and numbered 193; the other to J. O. Butler, No. 2029.

D. Smith.—1. When a patent is abandoned, the invention is open to the public, provided there is not another patent of prior date for the same thing. Any person is at liberty to patent improvements upon inventions, the patents for which have been abandoned. 2. "A communication" means that the invention has been communicated from *abroad* to the party in whose name the patent is taken. Inventions of persons resident in this country cannot be patented in the name of another party. 3. We cannot reply positively to your inquiry about eyelets.

To the Editor of the "Mechanics' Magazine."

Sir,—Perhaps you or some of your correspondents could kindly inform me of the best mode of welding domes for steam boilers, I mean the cylindrical parts. I find considerable difficulty in obtaining a heat sufficient for the purpose without burning the iron.

Birkenhead. A Boiler Maker.

[The method usually adopted in the best practice in such cases is as follows:—The plate having been bent to a rough approach to the cylindrical form, so that the edges approximate, is heated in the centre of its length, and being placed when removed from the fire, on a suitable mandril, has about four inches of the joint welded first, not a lap joint but one, technically known as a "butt," being the best. The welding then proceeds in successive heats from the centre towards each end. Care being taken to commence striking where the last weld finished. As to regulating the heat, we know of no better plan than that of placing a quantity of ordinary forge scale within the tube on the seam; this scale will bear a very high heat without becoming red-hot. When the iron has reached the proper welding heat, the scale just begins to melt, the test is regarded as infallible by old boiler-makers. We have seldom seen it fail.]—Ed. M. M.

To the Editor of the "Mechanics' Magazine."

Sir,—Will you please favour me, through the Mechanics' Magazine, how I can pour the mercury into a bent tube for a barometer? The difficulty to me is how to obtain a vacuum in the upper part of the tube, which is closed. An answer through your valuable paper will much oblige your obedient servant, G. A. T.

Wisbeach, June 3rd, 1863.

[The vacuum may be obtained by pouring a small quantity of mercury into the tube first, and boiling it. While boiling, the lamp is to be withdrawn, and the open end plunged into a vessel full of mercury, when, if the process has been properly conducted, the tube will fill to the top, provided it is not more than 30 inches higher than the level of the mercury into which the open end is plunged. The mercury should then be carefully boiled for a few minutes. The process is altogether one of considerable nicety, and requires some skill.]—Ed. M. M.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 2956, 2963, 2985.
Boilers and Furnaces, 2994.
Ships and Boats, including their fittings, 2950.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 2948, 2989, 2990.
Cultivation of the Soil, including agricultural implements and machines—*none.*
Food and Beverages, including apparatus for preparing food for men and animals, 2959.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 2947, 2951, 2955, 2971, 2972, 2977, 2978, 2981, 2984, 2995, 2998.
Buildings and Building Materials, 2973.

Miscellaneous, 2952, 2967, 2976, 2982, 2987, 2991.

2947. H. Williams and J. Maxton: *Improvements in machinery or apparatus employed in the manufacture of lace, or trimmings made on bobbin net or twist lace machines.* Dated October 31, 1862.

This invention consists in the employment of wheels, cut or constructed in such manner as to enable us to work either five or more warp threads, with one back warp thread and two bobbin threads. *Patent abandoned.*

2948. F. Gibson, T. Hall, and T. Davison. *Improvements in railway breaks.* Dated October 31, 1862.

This invention relates to several peculiar combinations of self-acting mechanism for applying railway breaks when the speed of the engine is checked, the consequent overrunning or crowding of the carriages in the train, and the inward movement of the several draw-bars, causing the application of the breaks to any or all the carriages or waggons in the train. According to one arrangement the breaks are fitted on to arms attached to a transverse rocking shaft, which rocking shaft is provided near the middle with a lever arm having a sliding piece thereon. This sliding piece is kept extended, so as to lengthen the arm by means of a spring or otherwise, but is held up when the break is not in action by the tail of a suspended lever or equivalent device acted upon by the draw-bar. Immediately beneath the end of the sliding piece on the lever there is a boss or collar made on the axle, and a notch or projection formed thereon. So long as the tractive strain of the engine acts upon the draw-bars and keeps them drawn out, the sliding pieces will be held up clear of the bosses or collars, but the moment the steam is shut off, and the speed of the engine is checked, the draw-bars run in and, by moving the tail of the suspended levers or equivalent device in the several carriages, allow the sliding pieces to descend and drop into the notch, or in front of the projection on the bosses, and being caught by them as they rotate, cause the lever and rocking shaft to be partially turned, and to apply the breaks. When the speed of the engine is increased again, the extension of the draw-bars lifts the sliding pieces and takes off the breaks again by the aid of a spring for that purpose. The bosses or collars above referred to may, if found desirable, form part of the nave or hub of the wheel, in place of being a separate boss on the axle. *Patent completed.*

2949. W. E. Newton. *Improvements applicable to the carriages and beds of guns, mortars, and other ordnance.* (A communication.) Dated October 31, 1862.

The nature of this invention consists in the use of india rubber for, and its application to, the trunnions of mortars, guns, or ordnance around them as bearings, and before and behind the carriages of mortars, guns, or ordnance on their beds, to resist the force of the recoil and reaction in firing. Also in the application and use of india rubber above and below, and before and behind, the beds of mortars, to resist the force of the recoil and reaction in firing. Also in the mode or method of checking the gun at the furthest limit of its recoil. And, lastly, in the use and application of an eccentric ring enclosing the india rubber round the trunnions of mortars. *Patent completed.*

2950. F. E. Sickels. *Improvements in steering and manœuvring ships or boats, and in apparatus connected therewith, which apparatus is also applicable for pumping or lifting weights.* Dated October 31, 1862.

This invention consists in improvements upon that kind of steering apparatus in which steam or other fluid under pressure is employed for the purpose of actuating the rudder, the object being to ensure increased efficiency and security in steering and manœuvring vessels. The apparatus for working the steering gear is also applicable for various other purposes, such as for pumping or lifting weights. When any great degree of rapidity in turning and manœuvring steam vessels is required, a forced draught to the furnaces (to increase the propelling power) should be combined with ample mechanical power to operate a large rudder. The steering engine is made to disconnect from the steering apparatus, and to connect with a hoisting drum, thus saving the room occupied by a separate hoisting engine for loading and unloading the vessel. When fresh water is required, an apparatus can be used to condense the steam that operates the steering apparatus, thus obtaining fresh water for the ship's company. If the steering apparatus be placed below the steam boiler which supplies it with power, a trap or other mechanism should be used to discharge the condensed water, either into tanks or overboard. To ensure the use of the least possible power required to operate the steering apparatus, the valve or valves which admit the steam or other fluid under pressure to the working cylinders is or are so connected with the steering apparatus that, while the steersman, by turning the wheel, opens the valve to admit steam to the cylinders, so as to cause the rudder to move, the steering apparatus, in moving, will give this same valve or valves a closing motion, and thus modify the extent of the opening of the valve and the rapidity of the admission of the steam or other fluid to the working cylinders. The power to move or hold the rudder is transmitted through an adjustable friction or connection, so as to limit the power transmitted from or to the rudder. *Patent completed.*

2951. J. G. Marshall. *Improvements in the treatment of straw of flax, hemp, and other similar substances preparatory to spinning the fibre thereof.* Dated October 31, 1862.

The patentee claims treating the straw of flax, hemp, and other analogous vegetable substances by the processes described, whereby retting, scutching, swingling, and heckling may be dispensed with. *Patent completed.*

2952. W. Jenkins. *An improved mode of, and apparatus for, cutting coal.* Dated October 31, 1862.

In performing this invention, the patentee saws or cuts the coal out in blocks of convenient size. In carrying out this part of the invention, supposing he commences at an angle that has been prepared for the purpose, he first drills one or more holes in the upper or other convenient part of one of the faces of the coal near the roof of the mine, in order to make an opening for the introduction of the saw or cutting instrument, with which he proceeds to cut down into the coal in a vertical or diagonal line from top to bottom. He then drills one or more holes in the other face of the coal, and at right angles to the former cut, and proceeds to cut down in a vertical or diagonal line from top to bottom as before. By this means a pillar of coal from 12 in. to 18 in. square, according to the desired size, will be divided from the seam, except at the top and bottom, from which, if desired, it may be easily detached by a lever, if it does not fall away by its own weight; or if desired, a saw-cut in a horizontal direction may be made to facilitate the removal of the block of coal from the bed or seam. In order to cut out the coal on this improved plan, he arranges the operations systematically, so as to be enabled to actuate by mechanical power the machines employed for the purposes of the invention. *Patent completed.*

2953. J. J. Anderson. *A new or improved mode and means for the production of leather from waste leather scraps in combination with india rubber, gutta percha, or other light substance, and new material to be used as leather and for other purposes.* Dated October 31, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

2954. W. Tarr. *An improvement in pianofortes.* Dated November 1, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

2955. J. W. Taylor. *Improvements in scouring or cleaning woollen, worsted, and cotton fabrics and other fibrous materials, and in the means or apparatus employed therein.* Dated November 1, 1862.

The fabrics or other fibrous materials to be scoured or cleaned are, as they pass from the wash liquor, conducted between a pair or pairs of rollers, covered with prepared india rubber, by which such rollers will effect an elastic pressure. The fabric or other fibrous material is by pressure conducted open, first, alternately through wash fluid, and between these rollers, until the dirt or other matter to be removed has been well loosened; and then the patentee forces clean water in streams or jets on to the fabric, or other fibrous material, and again passes it between such elastic pressure rollers, by which the scouring or cleansing will be fully effected. *Patent completed.*

2956. E. Field, M. Merryweather, and R. Merryweather. *Improvements in steam fire-engines, parts of which improvements are applicable also to other purposes.* Dated November 1, 1862.

This invention consists of a framed carriage mounted—when intended for land surface—on travelling wheels. At the hinder end of the frame is the boiler, in front of which is placed the steam cylinder and pump. The boiler consists of a vertical fire-box, with water and steam chamber above, from the lower plate of which descend a number of tubes, arranged around the entrance to the smoke-flue, the lower ends of some of them converging inwards to bring them into more immediate contact with the main body of the fire. Within these tubes are smaller ones, open at top and bottom, their upper ends being wide-mouthed or trumpet-shaped to facilitate the entrance and downward passage of currents of solid water, unaffected by the steam which rises externally around them. The exhaust pipe from the steam cylinder, on entering the chimney, passes downward to a chamber (the lower surface of which forms a baffle plate), whence the steam is projected upwards to increase the draught in the fire-box. Provision is made for cushioning the piston in the steam cylinder by causing it to pass beyond and close the main ports, the steam and exhaust being then led through a smaller channel capable of nice adjustment. Steam is admitted to the working cylinder of the engine by a slide valve acted upon by a smaller steam valve, which receives its motion from connecting rods attached to the piston rod of the engine. *Patent completed.*

2957. G. Haseltine. *Improvements in burial cases.* (A communication.) Dated November 1, 1862.

The patentee claims—1, Controlling, disinfecting, and deodorizing the gases as they escape from the coffin, by making holes or valves therein, and combining and confining with or over the said holes or valves the disinfecting or deodorizing material in some part of the coffin, which is to be otherwise air-tight. 2. Making a chamber, in combination with the coffin, for the purpose of holding the deodorizing and disinfecting material, and causing the gases to pass through the said chamber on their way out of the coffin. 3. The use of the valve in combination with the disinfecting and deodorizing chamber. *Patent completed.*

2958. E. Stevens. *Improvements in iron shelves, stands, and racks.* Dated November 1, 1862.

In constructing iron stands composed of a series of shelves one above the other, each shelf is supported by ornamental cast-iron brackets, at suitable distances apart from each other, which are either to be fixed to a wall, or they may be carried by cast-iron pillars or standards. These brackets stand out from the column or wall, and their outer ends are connected at the front of the stand to eight iron columns by screws or otherwise. At the foot of each column is a screw-thread, on to which a hollow globe or other suitable foot is screwed; this foot serves to regulate the height of the column, and also facilitates the fastening the stand to the floor. Across the top of such bracket grooves are formed at a suitable distance apart, to receive T-iron, the strips of T-iron being by preference to run the whole length of the shelves. The T-iron is received into the grooves, so that the top of the T-iron is level with the top of the brackets, and the strips of T-iron are held in their places by pieces of wrought-iron plate screwed on to the top of the bracket. *Patent completed.*

2959. W. E. Newton. *Improved apparatus for drying grain and other substances.* (A communication.) Dated November 1, 1862.

This invention consists in the combination of a series of sieves or grated platforms arranged one above another, and inclined in opposite directions within a tower or shaft, and an elevating apparatus by which the grain or other substance to be dried is carried up to the top of the tower or shaft to be deposited on the uppermost screen, or platform, or sieve. The sieves or platforms have imparted to them a shaking motion, by which the grain or other substance is caused to be distributed over and to run down the sieves or platforms from each to the one below it, while upward currents of air generally heated are caused to circulate in the tower or shaft, and through the sieves or platforms, and to absorb the moisture and carry it off at the top of the tower or shaft. From the lowest sieve or platform the grain or other substance is delivered into a suitable receptacle, whence it may be carried away to bins or other places; or, if not properly dried, may be taken and carried up again to the top of the tower or shaft to have the process repeated. *Patent completed.*

2960. E. Hopkins. *An improved method of, and apparatus for, treating ores, and for the extraction of metals therefrom.* Dated November 1, 1862.

The chief object of this invention is to effect by an economical mechanical process (the details of which process we cannot produce here) the separation of gold from its ores to such an extent that, when the ore is submitted to furnace heat to complete the separation of the gold, it will be presented in the form of a rich auriferous powder. *Patent abandoned.*

2961. J. Winter. *An improved safety tap or cock, applicable to gas burners, gas pipes, and vessels containing gas. Also water pipes, steam pipes, and vessels containing inflammable and other liquids, compressed air, and spiritous liquids.* Dated November 1, 1862.

This safety tap or cock is constructed as follows:—Through a square or other shaped piece of metal, the patentee forms two taper holes, in one of which he fits an ordinary plug or tap, and in the other a plug or valve, somewhat similar to an ordinary plug, but differing therefrom by making the outer end thereof or handle round instead of flat, and milling the edge thereof, so that, in order to turn this valve round in its seat, the milled part must be firmly gripped by the nippers. There is a spring attached to the valve for turning the same in its seat, and a spring bolt for holding the valve open, the said bolt being acted upon by the ordinary tap aforesaid. The essential feature of this invention consists in connecting the ordinary tap before mentioned with the valve aforesaid, or, in other words, in causing the tap when shut off to act upon the valve, thereby withdrawing the bolt and allowing the spring to turn the valve in its seat, and shut the passage through same, so that, in the event of the handle of the ordinary tap aforesaid being accidentally turned round, the valve aforesaid will remain closed until it is turned round by hand, as above stated. By the use of this self-acting valve, the escape of gas, compressed air, or other fluid or liquid, will be prevented, and security against accidents from explosion or fire and waste most effectually ensured. *Patent completed.*

2962. F. Tussaud. *Improvements in machines for cutting metals; also applicable to cutting other substances.* Dated November 3, 1862.

This invention consists in an improved construction or arrangement of circular metal cutting machines, by which sheets of metal, cardboard, leather, and other materials of great width and length, may be divided continuously, and curved or round shapes may be cut out, and is as follows:—For cutting in the middle of sheets of metal or other material, the ordinary circular cutters, having their edges bevelled or not as required, and slightly crossing each other, as usual, are mounted at the extremity of two long shafts or axles, suitably supported, the length of the axles varying according to the length of the sheet to be cut. A way or groove is formed in the framework of the machine for the passage of the cut metal or other material, so that, with a machine of small dimensions, large sheets of metal or other material may be divided in the middle. For cutting curved forms of small or large radius, the upper cutter is vertical, and is worked by the motive power; the axles of the lower cutter are independent of the mover, and are articulated so as to be adjustable at any angle to the upper cutter. *Patent completed.*

2963. J. Musgrave. *Improvements in the valves of steam hammers, and steam hydraulic and gas engines.* Dated November 3, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2964. C. Shield. *Improvements in the manufacture of malleable cast iron.* Dated November 3, 1862.

This invention consists in manufacturing malleable cast iron by injecting atmospheric air into or upon raw or crude metal (iron) in a molten state. *Patent abandoned.*

2965. L. Gonez. *A seat or chair forming also a travelling bag for the use of travellers by rail or other way.* Dated November 3, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2966. F. Trachsel and T. Clayton. *Improvements in machinery or apparatus for obtaining light, heat, and ventilation, parts of which improvements are also applicable to other purposes.* Dated November 3, 1862.

This invention has reference to a former patent dated March 15, 1861, No. 652. We cannot give space to the voluminous details of the invention. *Patent completed.*

2967. G. Hollins. *Improvements in the manufacture of straps and belts for machinery.* Dated November 3, 1862.

This invention consists in an improved mode of joining the single straps together. Instead of stitching them the entire length, the inventor stitches them at the joints only, and secures the intervening spaces by rivets, thereby rendering the double strap more pliable than those at present in use, and effecting a great economy of labour. *Patent abandoned.*

2968. E. Humphrys. *Improvements in the construction of centrifugal pumps.* Dated November 3, 1862.

This invention consists in casting the case in two pieces, the joint being made in a line passing horizontally through the axis of the wheel spindle and its stuffing-box and in casting the wheel and its spindle in one piece. In this manner the use of covers is avoided, the fitting is simple and easily accomplished, and in consequence of the line of the joint passing through the axis of the wheel spindle, the wheel is readily introduced or removed when necessary, the upper part of the case being unbolted and lifted for the purpose. *Patent completed.*

2969. W. Clark. *Improvements in castors and in the manufacture of the same.* (A communication.) Dated November 3, 1862.

In carrying out this invention the inventor makes the socket, which is fitted on the leg or other part supporting the furniture, with a bottom or disc disposed about or below the middle of its depth, and from the centre of such disc he raises a socket tube, which receives a pin or axis fixed in the plate, having the arms in which the roller or castor is fitted. This plate fits in the bottom of the leg socket, so as to turn freely therein. Between this bottom plate and the false bottom or disc of the leg socket before mentioned, he disposes a series of friction rollers, which transmit the weight of the furniture to the plate and arms carrying the wheel. These friction rollers are mounted on a sort of star-piece or series of radial arms, fitted on the centre pin of the castor, each arm forming an axis for one of the friction rollers. The leg socket is fixed in the ordinary manner, while the tube or socket receiving the centre pin passes to a greater or less length up the centre of the leg, and may or may not be used for further fixing the castor on the leg or furniture. By thus fitting the parts of the castor, it will move round easily, although under great pressure, and adapt itself readily to the direction it is desired to travel. The castor wheel may also be disposed more immediately underneath the table leg or other point of support. *Patent completed.*

2970. T. O. Clark. *An improved portable spring bottom bedstead.* (A communication.) Dated November 3, 1862.

In carrying out this invention, the inventor constructs the framework of the improved portable spring bedstead by preference of iron (it may be cast iron), with the side rails hinge-jointed to the ends of the bedstead, as also in the middle of their length, and so that they fold inwards—that is to say, the side rails fold or double, and may assume a position in a direction across and parallel, or nearly so, to the ends of the bedstead, which at the same time approach each other to within, say about 8 in. or 10 in. of each other in its collapsed form. The side rails are fitted with notches to receive the laths or stretchers suppporting the bed. These can be readily placed or removed from position; when in position they keep the frame rigid. From the laths or cross rails he supports the mattrass surface by a peculiar arrangement of springs distributed throughout the area of the bedstead, the lower parts being connected to the rails, and the other parts to longitudinal and cross webbings at the points of intersection thereof. We cannot here quote all the details. *Patent completed.*

2971. D. Scattergood. *Improvements in circular frames for the manufacture of looped fabrics.* Dated November 3, 1862.

This invention consists of certain arrangements of machinery in circular frames or "roundabouts," as they are termed in the trade, as hereinafter described, whereby shirts, drawers, hose, and other articles made thereon may be "fashioned" or "narrowed" in order to impart the desired shape to such articles without their being cut, and the parts united to form the "fashion," and whereby such narrowed goods are finished as far as the fashion is concerned before being removed from the same. The heads of the frames may be mounted to work in a vertical, horizontal, or inclined position, as desired. In order to produce the fashion, a certain number of needle plates or carriers with their needles are removed from the circle of needles, yet the same space between every two needles in the circle is preserved, while the needle-plates or carriers have constantly a bearing or support at back upon a hollow conical collar and conical supports, which are moved to present a circle of decreased diameter when needle-plates and needles are moved, and which are again moved in a contrary direction to afford bearings of increased diameter when the needles are replaced. The usual loop and dividing, landing, and knocking-over wheels are moved to perform their functions, whatever be the diameter of the circle of needle. *Patent completed.*

2972. P. F. C. Chevron and E. C. Eichenberg. *An apparatus for weaving India shawls and other figured tissues.* Dated November 3, 1862.

The object of this invention is a new method of manufacturing India shawls, carpets, and other descriptions of figured fabrics. The inventors accomplish this by producing by machinery the hooking "crochetage" which has hitherto been done in India by hand. For this purpose they dispense with a shuttle, and substitute for it needles and hooks, the combined action of which, facilitated by the play of supplementary weighted cords, and by a comb, the teeth of which are free at the top, produce the fabric. *Patent completed.*

2973. R. A. Brooman. *Improvements in machinery for moulding and compressing artificial fuel, peat, bricks, tiles, and other substances.* (A communication.) Dated November 3, 1862.

This invention consists in constructing and arranging, moulding and pressing, machinery as hereinafter described. Upon a bed the inventor erects a pillar for carrying the axis of an oscillating beam. To this beam, in front of the pillar, two pistons are connected, one at the end of the beam and the other near the pillar. One piston is used to compress and mould the substances in moulds carried on a revolving platform, and the other for driving the moulded or compressed substances out from the moulds. Where the shape of the moulds will not admit of the moulded articles being driven down through them, then he employs a piston from below to force them up through the moulds. This latter piston is made to move up and down by levers connected to the beam behind the pillar through a connecting rod. The revolving platform carries several moulds, and is made to revolve to present the articles, first to the moulding piston, and then to the piston for driving out the moulded articles. Motion is communicated to the outer edge of the platform, which is toothed for the purpose, through a paul and lever worked from the same prime mover, which, through a connecting rod, drives the oscillating beam. The moulded articles are carried away upon an endless belt. *Patent completed.*

2974. W. H. Stallard. *Improvements in umbrellas and parasols.* Dated November 3, 1862.

This invention consists of a novel mode of constructing umbrellas and parasols, whereby the same are combined with a walking stick, so that when shut up the stick forms the umbrella case. The peculiarity of this invention is that the stick upon which the umbrella is opened also forms the case in which it is contained. This hollow stick or shaft is closed at one end with a ferrule, and at the other end fitted with a handle, which opens upon a hinge, and is fastened and secured when closed by a lock snap and spring knob, or by a rotary collar with a groove or slot, or by any other suitable means. The umbrella frame and cover is made without any shaft or stick of its own, and thus folds when collapsed in a very small compass, and occupies a much smaller space than when constructed in the usual way with a centre shaft and runners. *Patent completed.*

2975. J. B. Francis. *Improvements in apparatus for raising and lowering window blinds, maps, and other articles for retaining them in position.* Dated November 4, 1862.

In Venetian blinds, maps, and other articles, it is customary to convey the cords by which they are raised and lowered over guide pulleys mounted on a fixed stud. This invention consists in mounting the said guide pulleys in a lever jointed to a box or frame; the cords after passing over the guide pulleys pass between the tail end of the levers and the inside of the box or frame; to the tail end of the lever is also attached a check cord. After the blind, map, or other article has been raised to the required height, it is retained in position by the weight thereof binding the cords between the tail end of the levers and the frame. In lowering the blind, map, or other article, the check cord has to be depressed to allow the cords to pass between the tail ends of the levers and the frame. *Patent abandoned.*

2976. J. Lefebvre. *Clitograph or instruments for indicating angles or variations of level, and for measuring horizontal and vertical distances.* Dated November 4, 1862.

In carrying this invention into practice, the patentee proposes to call the instrument made in accordance with the invention a "clitographe." Such instrument consists of a frame, which he prefers to make in iron, or other metal, by preference of a parallelogram shape. The frame has suspended from the centre of its upper side a pendulous arm or radial bar, to which a spirit level is attached at about the centre of its length, and so mounted as to be readily capable of adjustment and rectification; a line should be drawn vertically along the centre of the pedulous arm. At the lower part of the frame there may be either one, two, or more sectors on which there is engraved at the centre of their length a zero point, and the angles are marked right and left thereon, either as tangents or degrees and minutes, so that all angles, abscisses, and ordinates can be readily read off. The pendulous arm or radial bar may have a lip or guide-piece at its lower end working over the bottom sector, so that it may be kept in position or up to its work, this lip may form a vernier scale. *Patent completed.*

2977. F. Durand. *An improved cotton gin.* Dated November 4, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2978. J. McKean and T. Greenall. *Improvements in sizing or dressing yarns or textile materials.* Dated November 4, 1862.

This invention relates to the application or employment and use of a novel compound or composition for the purpose of sizing or dressing and preparing warp yarns for the loom or for sizing. The basis of this compound or composition is what is technically or commercially known as China clay, kaolin, or other similar siliceous or aluminous earths, and such clays are rendered available for use in the treatment of warp yarns by admixture with the products obtained from farinaceous or amylaceous matters, such as wheat, rice, potatoes, sago, tapioca, salop, or from any other available or practical source, after having been subjected to certain special processes. *Patent completed.*

2979. J. H. Johnson. *Improvements in hanging, arranging, and operating ordnance.* (A communication.) Dated November 4, 1862.

The essential feature of this invention consists in hanging or arranging any number of pieces of ordnance upon a suitable frame, revolving in a vertical plane, either by the aid of steam power, or otherwise, in such manner that the guns themselves with the frame shall travel through a portion of the whole circumference of a circle. This frame is further capable of revolving in a horizontal plane, both of which revolutions may be effected separately or together. *Patent completed.*

2980. T. Logan. *An improved kaleidoscope.* Dated November 4, 1862.

This invention consists, principally, in mounting the kaleidoscope on a stand in which it is supported with the eye-piece upwards, so as to be capable of revolving. Also in attaching a circular or other reflector to the said stand, mounted on pivots so as to be capable of being placed at a suitable angle to reflect the light into the kaleidoscope. *Patent abandoned.*

2981. J. Place. *Certain improvements in looms for weaving.* Dated November 4, 1862.

This invention relates to that part of the power loom known as the "treading motion," by which the rise and fall of the healds are effected. The improvements consist in the novel improvement and use of a double set of "treddles;" that is, one set hinged to the back rail of the loom, and projecting forwards, and the other set of a corresponding number hinged to the front rail, their ends projecting towards the others, so that such extremities may be coupled together by a link near the middle of the depth of the loom. The treddles so constructed are to be actuated by "tappets," of a suitable and peculiar form, and of less dimensions than those hitherto similarly employed, and so calculated as to render the "shedding" motion more positive. By this combination of small tappets and double treddles, looms may be driven at a higher speed, and a considerable improvement effected in the fabric. *Patent completed.*

2982. P. W. Reuter. *Improvements in dyeing.* (A communication.) Dated November 4, 1862.

In carrying out this invention, the inventor takes slacked lime in the proportion of 1 lb. to every 100 gallons of water, or thereabouts, and after the same has been well mixed, he takes the clear solution of lime and adds thereto powdered oxide of lead, litharge, minium or massicote, or other salt or compound of lead, in the proportion of about 2 oz. to every lb. of wool or woollen fabric to be dyed. He then adds carbonate of soda in the proportion of about 1 oz. to every lb. of wool or woollen fabric to be operated upon. Having thus formed the bath or mixture intended for the dyeing or colouring of wool or woven fabrics thereof, he proceeds as follows:—The mixture or bath being contained in a suitable vessel, he places therein the wool or fabric to be dyed, and he gradually raises the temperature of the mixture or bath to 150 deg. Fahrenheit, and after the wool or other material or fabric to be dyed has attained the desired intensity of colour or tint, he removes it from the dye bath. It may then be removed and dried, but generally it is preferred to subject it to what is known as a "soap bath," and afterwards to a bath containing water acidulated with hydrochloric or other suitable acid; and, finally, to several washings in cold water, as is well understood. By this means, any lime or other substance which may become attached to the wool in the process of dyeing is removed. *Patent completed.*

2983. T. Huntley. *Improvements in kitcheners and kitchen ranges, and in cooking and bath-heating apparatus.* Dated November 4, 1862.

In carrying out this invention, the patentee, first, forms the whole of the parts which fit together, and which are usually fastened with screws and other similar media, with male and female flanges, or tongue of groove or lap-over joints. This improved form of joint gives strength to the plates by the flanges. Ranges thus constructed can be made more readily, and can be more easily put up and removed when required, than as heretofore constructed. Greater facility is also afforded for repairs, and the liability to breakage, consequent upon the corrosion of all screw fastenings, is avoided. Secondly, he forms the fire grate, flues, and dampers, and so constructs and places the ovens and other parts of the apparatus, that the products of combustion from the fuel in the grates are converted into a clear heat, free or nearly so from smoke, and which heat or product of more perfect combustion, is concentrated upon any part of, or entirely disseminated through, the apparatus, thus economizing the fuel necessary to produce the required degree of heat, while the less quantity of smoke passing through the flue prevents the usual accumulation of soot and the coating of the surfaces of the parts of the apparatus therewith, whereby the draft is impeded, the effective action of the heat is diminished, and the operation of the apparatus retarded. Thirdly, he dispenses, where the service is constant, with the necessity for any house tank or intermediate feed cisterns, and all kinds of water vessels (hot or otherwise), together with the usual complicated mechanism for bath-heating, by the substitution of an improved construction of steam and water boilers, which together with the other parts of the improved apparatus (except the supply and service pipes) are all adapted to and contained in the fire-place or chimney opening. *Patent completed.*

2984. R. A. Brooman. *Improvements in the manufacture of fringes, and in machinery employed therein.* (A communication.) Dated November 4, 1862.

This invention consists in manufacturing fringes by machinery, and in certain arrangements of machinery hereafter described, whereby hand labour is dispensed with in the manufacture of fringes. The inventor employs a frame with shafts, cams, and toothed gear, for imparting the necessary motions to the various parts of the machine. He employs a disc or frame for carrying bobbins of silk, worsted, or other material of which the fringe is to be formed, and imparts rotary and stop motions thereto for allowing of the threads from the different bobbins being wound off at the proper moment. The threads may be of different colours; and in addition to them, he uses a warp thread. The machine being set in motion, the disc with its bobbins turns upon its axis as well as a guide through which the threads from the bobbins pass to a hook, which, seizing hold of the thread, recedes with it and doubles it, in the length required for the bullion or twist, allowance being made for the shortening consequent upon the twisting. At this part of the operation, a presser comes upon and tightens the work previously made. The doubling hook delivers the thread doubled to a twisting hook, which partakes of rapid rotary motion, which motion is interrupted twice by means of a tappet. The first interruption is to allow of the rotating hook taking the thread from the doubling hook, and the second to allow of the bullion or twisted fringe being unhooked from it. This unhooking is effected by nippers, which transmit the fringe between a drum and rails, an endless belt facilitating the advance of the finished fringe. During these operations the bobbin disc has performed part of a revolution, and has presented a bobbin with thread of a different colour, to be acted upon by the doubling hook and other parts, as before described. *Patent completed.*

2985. J. Shirt. *Improvements in apparatus for condensing the steam of high-pressure steam engines.* Dated November 4, 1862.

For the purposes of this invention an air-tight chest or vessel is applied to the exhaust pipe of a high-pressure steam engine; above the point where the exhaust pipe is applied to the chest or vessel, there is a perforated partition, or other provision is made for dividing the condensing water into numerous streams. The condensing water is introduced by a pipe at the upper part of the chest or vessel from a cistern or otherwise, so as to keep up a constant supply, which may be regulated by a cock or valve. From the lower part of the chest or vessel, a waste water pipe descends, and the lower end of such pipe is constantly covered with water in a well or cistern or other vessel. The exhaust steam flows from the steam engine into the air-tight chest or vessel, and is there condensed, whilst the steam in the engine acts on the piston, which, on the other side is subject to a partial vacuum. *Patent completed.*

2986. J. E. F. Ludeke. *Improvements in magneto-electric apparatus for obtaining and applying motive power.* Dated November 4, 1862.

One form of apparatus, according to this invention, consists of a square foundation plate, having four vertical standards supporting a table, from the under part of which is suspended, by means of two rods, a double bar of brass, between which a series of permanent horseshoe-magnets of five or other number are clamped and held firmly in an inverted position by means of nuts and screws. A corresponding double brass bar of smaller dimensions serves to clamp in like manner a similar series or number of flat iron needles or pointers, the points of the needles standing vertically uppermost, and the lower part or flat head forming the armatures for the magnets. This double bar is suspended by rods, and moves either on a pivot, knife edge, or hinge. In the centre of the table is suspended a pendulum, the rod of which is formed like a double fork, the prongs of which pass on each side of the magnets, and at the needles and at the central part of this fork the metal is enlarged to allow of a horizontal pivot being inserted, which passes through the centre of the double bars of the magnets, the pendulum itself reaching almost to the foundation plate. On each side of this pendulum are arranged pillars, on which are supported bell-crank levers, which give motion and alternate vibration to the pendulum by means of descending levers from the bell cranks, which are provided at their lower part with small friction wheels to act against the surface of the pendulum. The extremity of the horizontal arms of the bell-crank levers pass one in front and the other behind the pendulum, and there is attached to each a wire or cord ascending to the bars of the needles, and secured thereto one on each side by means of a stud or projection. Thus, it will be evident that, as the pendulum vibrates from side to side, together with the magnets, the needles will be magnetized by the north and south poles of the magnets alternately passing under them, by which the needles will be attracted and drawn alternately towards the north or south pole (the apparatus standing in a direction to allow of the line of magnets lying due east and west). This alternate rocking motion of the needles and their double bar actuates the studs on each side thereof, and consequently draws each cord or wire alternately upwards, whereby the descending arm of each bell-crank lever is simultaneously forced against the side of the pendulum, thereby producing a continuous motion. of the apparatus. *Patent abandoned.*

2987. A. E. Davies. *An improved lubricator.* Dated November 4, 1862.

In carrying out this invention, the patentee take a glass or other vessel of any convenient, and, if desired, ornamental shape—for example, a glass phial—and into the neck thereof he fits a stopper of cork, or other suitable material, air-tight. Through this stopper passes a small metal tube, open at one end and closed at the other end. He punctures the closed end at its centre with a fine point, and on the side of said tube, at a short distance from the aforesaid stopper, forms another fine hole. He then proceeds to withdraw the said stopper with its attached tube, and nearly fills the phial with the lubricating fluid, which should be very limpid. He then inserts the stopper aforesaid, taking care to place the punctured end of the tube thereof within the phial, leaving the open end of the said tube outermost. Having done this, he inverts the phial, the object of which will be that the air contained in the uppermost part of the phial will force out the lubricating matter through the hole in the side of the tube, the lubricating matter passing out at the open end of the tube. Now, supposing this open end of the tube to be placed over the journal of an axle, shaft, spindle, or other rubbing surface, as the same rotates or reciprocates, the effect will be to aspire the lubricating matter from the vessel containing the same, and thereby cause a partial vacuum in the said vessel, so that, when the axle or other rubbing surface is not rotating or reciprocating, the lubricating matter will be kept up within the tube by capillary attraction, and, as the axle or other rubbing surface again rotates or reciprocates, a portion of atmospheric air will pass up the tube aforesaid through the punctured end thereof into the upper part of the glass vessel, and again displace a proportionate quantity of the lubricating matter, and so on successively, thereby only discharging the lubricating matter during the rotations or reciprocations of the axle or other rubbing surfaces, and preventing the escape and waste of the lubricating matter when the axle is at rest; and it is this peculiar principle of construction which constitutes this invention. *Patent completed.*

2989. J. B. Thomas. *Improvements in apparatus for working and controlling railway signal discs.* Dated November 5, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

2990. S. Robotham. *Improvements in carriage bodies.* Dated November 5, 1862.

This invention relates to carriage bodies, and has for its object an improved manufacture of the back and arms part thereof, or the part forming the back and arms of the body. For the purposes of this invention, the inventor constructs a framework or outline of the desired shape, and similar to the construction hitherto used for the support of japanned leather and other materials, and this framework or outline he fills in with ductile sheet metal. He takes plain, perforated, or embossed sheet metal. If plain, he cuts a blank and shapes it on a block, pressing it or beating it into form. He then finishes it by hammering or otherwise. Heat may be applied to anneal or facilitate the manipulation. *Patent abandoned.*

2991. J. Banwell. *Improvements in apparatus for punching by means of hydraulic pressure.* Dated November 5, 1862.

This improved apparatus consists in applying to a suitable ordinary jaw or holder a hydraulic cylinder, with ram working therein, the outer end or front of which ram has the punch affixed thereto. This ram is hollowed out, and the hollow part is provided with a piston which can slide on a piston rod, the piston being screwed so as to act in the hollowed part of the ram, which is also screwed to correspond. By these means the inventor advances the piston, and the ram is thereby advanced by the hydraulic pressure in the cylinder resulting from this action. The punch in front of the ram is thus put to work, and acts upon the metal or material placed in the jaw or holder. The end of the hydraulic cylinder at back of the piston is to be secured by being screwed into the same, and to have an orifice for the piston rod to work through. The piston rod is moved by a lever hand or driving wheel. *Patent abandoned.*

2992. W. Johnson. *Improvements in the arrangement and construction of pillars or standards for supporting telegraph wires.* (A communication.) Dated November 5, 1862.

This invention relates to the arrangement and construction of the pillars used for supporting the wires of electric telegraphs. Under one modification, the standard consists of a cast or wrought iron pillar and socket, the lower part of which is formed with three radially projecting feathers, extending from the bottom up to the part which projects above the ground. The base is formed in this manner in order that the pillar may be fairly held in the ground when the earth is properly rammed in between the flanges. That portion of the pillar which fits into the socket and extends above the earth, may be either of a cylindrical, cruciform, angular, or polygonal figure in its cross-section. At the upper extremity of the pillar is fitted a cross-head, having two or other number of radially-projecting arms, in which are carried the insulators for insulating the telegraph wires; one of these insulators is also, if required, fitted in the centre of the cross-head. On the under side of the cross-head lugs are cast, and each lug is perforated to admit of connecting thereto a wire or rod, which is carried down to a corresponding lug in the socket at the foot of the pillar immediately above the earth. These stays or guy rods serve to stiffen the pillar, and give it the necessary strength to resist lateral pressure. Another arrangement of the socket consists of a foot-plate made with radial arms, from which extend in an upward direction stays supporting a disc, arranged a little above the surface of the earth. The telegraph pillar is passed down through a suitable aperture in the disc, and stepped into the foot-plate, and the stays or guy rods are fastened to hooks projecting out from the periphery of the disc. *Patent abandoned.*

2993. R. A. Brooman. *Improvements in commodes or water-closets.* (A communication.) Dated November 5, 1862.

This invention applies to portable as well as fixed closets, and consists in the arrangements of parts hereafter described. At the back or side of the basin is a water cistern; at the bottom of this cistern there is a cylinder, forming a pump barrel, and in this barrel a piston with valves, opening only when the piston is raised, is fitted. The outlet from this barrel is into a pipe opening into the basin. A rod is connected to this piston, and carries a handle which passes through the cover of the cistern. Two studs are fixed in the piston rod, between which the forked ends of a bent lever are placed; the other end of this bent lever is connected through a link and connecting rod to a shaft, on which the valve at the bottom of the basin is fixed. On raising the piston rod, this valve is opened, and at the same time water passes through the valves in the piston and below it. On releasing the piston, and allowing it to descend by its own weight, or assisting its descent by pressure, the valve in the bottom of the basin is closed, and the water under the basin is sent by it into the basin. *Patent completed.*

2994. R. A. Brooman. *Improvements in taps or cocks.* (A communication.) Dated November 5, 1862.

This invention consists in constructing taps and cocks as hereafter explained. A flexible diaphragm is secured in the flanges of a cap, with a solid disc of metal or other hard material fixed in the upper part thereof; a partition rises inside the tap, and forms part of the seat for the diaphragm when pressed down on the mouth of the inlet to prevent the passage of liquid. Pressure is exerted upon the diaphragm through the metal disc by an eccentric or cam pivotted on and working through the cap; the eccentric is fitted to the end of a hand lever; or a cam or heart block may be fitted to the lever of a float; or the diaphragm may be depressed by a screw; or a weighted beam may be used to press upon a rod in contact with the disc. In order to allow of liquid passing through the tap, pressure must be removed from the disc and diaphragm, when the liquid will raise the diaphragm off its seat, and, following it up, will pass over the partition in the tap and flow out. By using a circular bar with apertures, and fixing the lever carrying the eccentric in one or other of the apertures, the quantity of liquid flowing through the tap may be regulated. For water posts the pressure may be removed from the diaphragm by raising a handle fixed in a rod working through a nut. *Patent completed.*

2995. R. A. Brooman. *Improvements in spinning frames.* (A communication.) Dated November 5, 1862.

This invention consists in imparting to every separate spindle, or to every two spindles coupled in continuous spinning frames, up and down motions, whereby, for any purpose required, every such spindle or pair of coupled spindles may be stopped or taken out of work, and again returned into work without interfering with, or stopping the motion of, the rest or of any other portion of the spindles in the frame. *Patent completed.*

2996. J. C. Shield. *Improvements in the manufacture of malleable cast iron.* Dated November 5, 1862.

This invention consists in the manufacture of malleable cast iron by passing, in suitable quantity, on to or through raw or crude iron, partially refined or refined iron, when in the molten state, a current or currents of atmospheric air or steam, or of air and steam, or any other decarbonizing gas; the steam being either superheated or otherwise, and the air or other decarbonizing gas at any temperature. When the decarbonization is pushed beyond the limit desired, he adds in proper quantity, to the mass thus obtained, crude or raw iron, partially refined or refined iron, or any substance suitable for imparting a fit proportion of carbon. *Patent completed.*

2997. A. V. Newton. *A new process of obtaining printing surfaces, dies, and substitutes for photographic negatives.* (A communication.) Dated November 5, 1862.

The principal feature in this invention consists in first making a drawing in ink, which is soluble in water, upon the surface of a plate of glass or any other hard substance which has been previously coated with an alcoholic solution of shellac; then covering the whole surface with a coating of bees-wax, or of a composition of bees-wax, asphaltum, and linseed oil, or other menstruum; next, immersing the plate in water for some time, and afterwards exposing its face to the action of a stream of water, by which the latter coating is washed off only from the lines of the drawing, and the whole of the drawing itself is washed away, leaving the latter coating between and among the lines of the drawing. The plate in this condition can be used in the same manner as a wood engraving to obtain an electrotype for printing, and with very little subsequent preparation for the other purposes specified. *Patent completed.*

2998. J. Petriel and J. Teal. *Improvements in machinery or apparatus for washing wool and other fibrous materials.* Dated November 5, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2999. S. Tragheim. *Improvements in treating hemp, preparatory to its being spun.* Dated November 5, 1862.

This invention consists in a mode of treating hemp in order to manufacture therefrom a substitute for cotton and wool. For this purpose the hemp is subjected to the various processes after mentioned. The inventor takes a quantity of hemp, and places it in a suitable vessel, to the bottom of which is brought a steam pipe, and the hemp is saturated with steam till it is softened sufficiently for the next process. The softened hemp is then hackled, till the fibres split up into numerous parts. The hemp is hackled to the same extent as when it is wanted to be used as yarn, as heretofore. The product is next subjected to the operation of the machine used in cotton manufactories, and known by the names of a "devil," by which the hemp will be torn up, and lose the appearance of hemp. The product is soaked in water which has been prepared in the following manner:—A quantity of chloride of lime is put at the bottom of a vessel, and lukewarm water poured on to it. The chloride of lime is not stirred, but after the water has remained for an hour or two it is run off and applied in a suitable vessel to the hemp. The hemp is to remain in this liquid until it is well saturated; it is then taken out and washed in cold water, and then dried. The product is next to be subjected to the bleaching process like yarn, and dried. The product is then passed through a carding engine, and comes out a substance which, if the hemp used has been Riga hemp, is similar to cotton; and, if it has been St. Petersburg hemp that has been used, it resembles a mixture of cotton and wool. The nature of the product in each case will depend on the class of hemp employed. *Patent abandoned.*

3000. D. Hill. *Improvements in apparatus for stamping or marking and counting bank notes and other documents.* Dated October 5, 1862.

For the purpose of this invention, two counting apparatus are combined with a stamping or marking press, and they are both actuated each time the press is actuated to produce an impression. One counting apparatus is accessible to the user of the press, or to another person, in order that such counting apparatus may be set at zero at the commencement of the use of the press on one of the several bundles or quantities of bank notes or other documents, whilst the other counting apparatus is enclosed, and is only set at zero at the commencement of a day's work or other regulated period. The arrangement of the stamping or marking press may be varied; and such is the case in respect to the two counting apparatus combined therewith; and separately, no claim is made to their construction. *Patent abandoned.*

3001. J. J. Laveissiere. *Improvements in the manufacture of tubes of copper or other metals or alloys.* Dated October 5, 1862.

This invention relates to the process of manufacturing tubes from hollow ingots or cylinders of the metal or alloy. In order to obtain a sound hollow ingot or cylinder of the metal or alloy, the patentee runs into a mould of the shape required for the exterior of the ingot the requisite quantity of the melted metal or alloy, it being either poured in at the top or run in at the side, and as soon as the metal or alloy has nearly, but not completely set, a mandril is forced down into the metal. This is effected by means of a screw or otherwise; the mandril is not, however, forced quite to the bottom of the mould, so that one end of the ingot will be closed; or it may be made with an internal flange only at its end. The metal is thus compressed, and the volume displaced by the mandril is caused to rise up around the core and to fill the mould. As soon as the metal or alloy has sufficiently set to retain its shape, the mandril is raised from the mould. In order to draw out the hollow ingots into tubes, he employs a system which allows of the metal being worked hot or cold. *Patent completed.*

3002. T. Brown. *Improvements in machinery for surfacing fibrous materials.* (A communication.) Dated November 5, 1862.

The inventor claims the use of a metallic apron, in combination with heating and cooling surfaces, to carry and apply surfacing material to, and dry the same on, a sheet of fibres, so as to surface the same, as explained. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated April 2, 1863.

845. W. H. Phillips, Nunhead, Surrey, engineer. Improvements in means or apparatus for cleaning the bottoms of ships or other floating vessels.

Dated April 20, 1863.

981. C. Blanc, civil engineer, 8, Rue Chapon, Paris. Improvements in apparatus for the purpose of using air and steam as motive power.

983. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in lamps. (A communication.)

Dated April 22, 1863.

1005. J. Lee, weaving master, and E. Dawson, foreman mechanic, Tammerfors, Finland. Improvements in looms for weaving.

Dated April 24, 1863.

1021. P. Passavant, Bradford, York. Improvements in the manufacture of blue colouring matter, and also of violet colouring matter. (A communication.)

Dated April 25, 1863.

1035. L. A. J. Bruet, Paris, clockmaker. Improvements in apparatus for registering, indicating, and verifying the time and distance passed over by vehicles, also applicable to machinery and other similar purposes.

Dated April 27, 1863.

1057. A. Rollason, East Peckham, Surrey, chemist. Improvements in dyeing and staining fabrics, parts of which improvements are also applicable for dyeing, staining, and ornamenting glass and other substances.

Dated May 5, 1863.

1121. F. Applegate, Bradford-on-Avon, woollen manufacturer. Improvements in stopping and starting railway trains.

Dated May 6, 1863.

1137. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improvements in sewing machines. (A communication.)

Dated May 7, 1863.

1139. J. Snider, jun., Dorset-street, merchant. Improvements in breech-loading firearms and ordnance.

1141. J. Walker, Crompstall-bridge, near Stockport, Chester, mechanic. Improvements in the construction of mechanism applicable to looms, and partly to carding engines and other machinery.

1145. J. Bettridge, Birmingham, Warwick, manufacturer. Improvements in the ornamentation of papier maché and other japanned wares, wood, ivory, and other similar materials.

1147. J. B. P. A. Thierry, engineer, 91, Rue des Marais, St. Martin, Paris. Improvements in the arrangement and construction of furnaces to render the combustion of the fuel more complete, and to prevent the emission of smoke therefrom.

Dated May 8, 1863.

1149. P. J. Livsey, Manchester, consulting engineer and patent agent. Improvements in compound engines. (A communication.)

1153. C. L. Braithwaite, Kendal, Westmoreland, manufacturer, and J. Hirst, manager. Improvements in machinery for feeding slivers of wool and other material to carding engines.

1155. J. C. Droop, tool manufacturer, Schwelm, Prussia. An instrument or holder for holding nails, screws, or other fastenings.

1159. G. T. Bousfield, Loughborough-park, Brixton. Improvements in steam engines. (A communication.)

Dated May 9, 1863.

1160. W. Thomson, Coatbridge, Glasgow, locomotive engineer. Improvements in obtaining motive power, which improvements are applicable in part for raising or forcing fluids into steam boilers, tanks, and other vessels.

1161. J. Strickland, 25½, Gee-street, St. Luke. Improvements in laying veneers on to surfaces, in applying the glue for that purpose, and in the apparatus employed.

1165. J. Page, Birmingham, manufacturer, and A. T. Wayne, tool maker. An improvement or improvements in the manufacture of pens.

1166. J. Brierley, Denby Dale, near Huddersfield, dyer. Improvements in dyeing knickerbocker yarns and textile fabrics manufactured of or from such yarns.

1167. W. Boaler, 85, Piccadilly, Manchester, merchant. An improver dryer fabric for paper-making.

1171. J. B. Wood, Vernon House, Camp-street, Broughton, near Manchester, M.D. Improvements applicable to the defending of ships or vessels and forts when armour-plating is employed.

1173. C. H. G. Williams, Burnford-street, Glasgow. Improvements in the manufacture of colouring matters.

Dated May 11, 1863.

1177. B. Hargreaves, Arden House, near Accrington, Lancaster, gentleman. Improvements in tiles for drainage or sanatory purposes.

1179. C. Shorrock, manufacturer, and W. Shorrock, manager, Over Darwen, Lancaster. Certain improvements in power looms for weaving.

1183. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in coupling and disconnecting carriages on railways, and in machinery employed therein. (A communication.)

1184. J. S. Guirette, Paris, doctor of medicine. An improvement in inhaling-apparatuses.

1186. J. E. McConnell, Dean's-yard, Westminster, civil engineer, and G. H. Bovill, Durnsford Lodge, near Wandsworth, civil engineer. Improvements in chains for cables and other purposes.

Dated May 12, 1863.

1187. B. Lilly, Birmingham, brass founder. Improvements in the construction of "snap-caps" or "nipple protectors" for firearms.

1189. T. Warren, Glasgow, glass bottle manufacturer. Improvements in glass and other furnaces and kilns.

1191. J. E. McConnell, Dean's-yard, Westminster, civil engineer, and G. H. Bovill, Durnsford Lodge, near Wandsworth, civil engineer. Improvements in treating worn-out railway tyres.

1193. G. A. Huddart, Brynkir, Carnarvon, gentleman. Improved apparatus for cutting slate.

1195. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in spring mattresses. (A communication.)

Dated May 13, 1863.

1199. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in laying submarine telegraph cables. (A communication.)

1201. T. Parkinson, Blackburn, Lancaster, engineer, and F. Taylor, foreman. Improvements in machinery for weaving, sizing, dressing, and dyeing.

1203. J. E. McConnell, Dean's-yard, Westminster, civil engineer, and G. H. Bovill, Durnsford Lodge, near Wandsworth, civil engineer. Improvements in the manufacture of thick plates of wrought iron for armour plates and other purposes.

1205. C. L. Kensner, East Greenwich. Improvements in the manufacture of hydrate of barytes, and in the manufacture of sugar.

1207. A. G. Southby, Bulford, Wilts, engineer. Improvements in railway roof lamps, station, signal, and other fountain lamps.

1208. J. Farmer, Salford, Lancaster, machine maker. Improvements in calendering, embossing, and other such machines used for finishing woven fabrics, part of which improvements is also applicable to drying machines.

1209. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in the extraction of hydro-carburets from minerals, in the distillation thereof, and in apparatus employed therein. (A communication.)

Dated May 14, 1863.

1211. J. Satchwell, W. H. Ashford, and C. Harrison, Birmingham, factors. Improvements in nails or rivets for boots and shoes, applicable to other purposes.

1213. J. T. King, Liverpool, patent agent. Improvements in wicks for oil and other fluid burning lamps. (A communication.)

1215. G. Dowler, Birmingham, manufacturer. An improvement or improvements in match boxes.

1217. F. K. Erlam, Devonshire-terrace, Fulham-road. A new lubricating material or compound.

1219. I. Parker, Houghton-street, Clare-market. Improvements in connecting and securing door and other knobs or handles to their spindles.

Dated May 15, 1863.

1220. B. Shillito, engineer, and D. Moor, merchant, 51, High-street, Kingston-upon-Hull. Improvements in generating heat and motive power.

1221. D. M. Fyfe, Maidenhead, Berks, Adjutant of the 19th Regiment of Berks Volunteers. Improvements in the brushes, instruments, or apparatus employed for painting the centres and bulls'-eyes of military or other targets.

1222. D. M. Fyfe, Maidenhead, Berks, Adjutant of the 19th Regiment of Berks Volunteers. Improvements in the means or apparatus employed for raising, removing, transporting, and refixing military and other targets or mantlets.

1223. W. Clark, 53, Chancery-lane, engineer and patent agent. Improvements in repeating firearms.. (A communication.

1224. A. Macmillan, 17, King's-road, Ball's Pond-road, Islington, tailor and clothier. Improvements in buttons, and in fastening buttons to garments.

1227. J. Papin, shoemaker, C. Lintz, and L. Lavacherie, 28, Rue Feydeau, Paris. Improvements in the manufacture of boots and shoes.

Dated May 16, 1863.

1230. J. Hinks, Birmingham, manufacturer. Improvements in lamps.

1232. F. M. Burns, Chorlton-upon-Medlock, Lancaster. Improvements in preventing the fouling of the bottoms and sides of ships and vessels, particularly applicable to ships and vessels constructed of or sheathed with iron.

1233. W. Clark, 53, Chancery-lane, engineer and patent agent. Improvements in rotary engines. (A communication.)

1234. J. T. Newton, Ystalyfera, near Swansea. Improvements in machinery for planishing and rolling sheet metal.

1235. J. Gibbs, Abingdon-street, Westminster. Improvements in preparing and spinning flax and other vegetable fibres and filaments, and in machinery employed therein.

1236. W. White, Leicester, manager. Improvements in machinery or apparatus for the manufacture of looped fabrics.

1238. E. B. Wilson, 5, Parliament-street, Westminster, engineer. Improvements in the manufacture of iron and other metals, and in the apparatus employed therein; parts of which are applicable for other purposes where high temperatures are employed.

Dated May 18, 1863.

1240. E. Christmas, Watford, Hertford, coach builder. Improvements in carriages for common roads.

1242. H. Bennett, Wombridge Iron Works, Salop, ironmaster. Improved apparatus or mechanism to be used for facilitating the puddling of iron.

1246. S. Toy, Birmingham, engineer. Improvements in machinery for making screw rivets, nails, or pins.

Dated May 19, 1863.

1252. F. Fenton, Mappleton, Derby. Improvements in the treatment of certain vegetable fibres for the preparation of textile materials therefrom.

1256. A. Parker. Billericay, Essex. An improved apparatus for saving from destruction by fire persons and property in houses, buildings, and ships, and also for ventilating ships. (A communication.)

1258. T. P. Salt, Birmingham, surgical instrument maker. Improvements in the manufacture of trusses.

Dated May 20, 1863.

1262. J. Coignard, Nantes, France, watchmaker. Certain improvements in sewing machines.

1264. P. Addington, Phipps-bridge, Merton, Surrey, varnish maker. Improvements in the manufacture of varnishes.

1266. T. Williams, 231, Bolling-street, Bowling, Bradford, York, and I. Naylor, 13, St. James'-square, Horton, Bradford, worsted spinners. Improvements in paper spools or tubes used in spinning and doubling machines.

Dated May 21, 1863.

1270. W. Walker, Manchester, agent and manufacturer. Certain improvements in looms for weaving.

1272. W. Nunn, 179, St. George-street, St. George's-in-the-East, manufacturer of ships' and other lamps and signals. Improvements in the construction of signal lanterns and lamps.

1276. A. Thomalley, Burgh-le-Marsh, Lincoln, brick manufacturer. Improvements in brick kilns.

1278. E. Sonstadt, Loughborough, Leicester. Improvements in the manufacture and purification of the metal magnesium.

1280. J. Goodman, Blackfriars-road, mechanician. Improvements in velocipedes, and in the construction of wheels for the same and other carriages.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated May 22, 1863.*

1282. W. Snell, 16, Clement's-inn, Westminster. Improvements in butt hinges. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, June 2, 1863.

165. B. Van der Mark. Musical instrument.

178. A. Phillips. Weaving figured fabrics.

189. Sir C. Lindsay. Apparatus to be used on railways to indicate to the engine driver of a carriage-train the length of the time which has intervened since the passing of a previous train.

204. C. Lungley. Facilitating the repairs of ships and other structures.

206. J. Milner. Steam engines.

210. F. N. Gisborne. Communicating signals on board ship.

211. W. Clark. Mariners' compasses. (A communication.

222. A. J. Sax. Rendering drum-skins and gut-strings less liable to hygrometric influences.

224. F. Tolhausen. Weaving ribbons. (A communication.)

230. A. L. Liétout and J. B. Roisin. Gymnastical apparatus.

260. H. Crichley. Reaping and mowing machines. (A communication.)

273. G. Blake. Heating and warming.

292. F. G. Grice. Manufacture of bolts, spikes, rivets, and screw blanks.

295. A. Forbes. Soldering together parts of vessels formed of tin or tinned plate.

296. W. C. Barnes. Shaping, rolling, or compressing metal.

314. G. T. Bousfield. Improvements in postage, revenue, and other stamps, and in apparatus for postmarking and cancelling postage and other stamps. (A communication.)

315. J. J. Hays. Hot air stove.

326. H. Dircks and J. H. Pepper. Exhibition of dramatic and other like performances.

328. R. A. Brooman. Supplying and spreading wool and other filamentous materials on belts, tables, and other surfaces to be afterwards carded and otherwise acted on. (A communication.)

337. R. A. Brooman. Carding engines. (A communication.)

365. **M. Wigzell.** Machinery or apparatus and method to be used in the manufacture of every description of candles, tapers, and other lights.

367. **W. Whitaker and W. Tongue.** Steeping, boiling, washing, bleaching, and dyeing fibrous materials and slivers, slubbings, rovings, yarns, or woven fabrics of the same.

426. T. W. Salmon. Washing machines.

430. J. Gimson. For punching or cutting out leather and other substances.

457. **W. Trustrum.** Manufacture of oiled silk.

487. J. Eckersley. Spinning and doubling silk.

528. **T. V. Lee.** Machinery for digging, compressing, and moulding peat or turf, and for retorts and kilns for drying peat or turf, and making peat or turf charcoal through the agency of hydro-caloric or superheated steam, and for collecting the products of distillation whilst charring the peat or turf.

559. W. Clark. Pumping and forcing water. (A communication.)

598. **D. D. Parsons.** Reaping and mowing machines. (Partly a communication.)

682. C. T. and A. Lutwyche. Metallic pens.

965. J. and T. Richmond and D. Harling. Looms.

974. T. A. Weston. Ratchet levers.

976. G. A. Buchholz. Hulling grain, and for reducing granular substances.

983. W. E. Newton. Improvements in lamps. (A communication.)

1033. J. P. and E. B. Nunn. Hoes and cultivators.

1043. A. V. Newton. Breech-loading firearms. (A communication.)

1058. H. Beare. Thrashing out corn from its straw, and also applicable for combing the straw.

1060. J. and W. Morris. Breaking loaf sugar.

1075. J. Rowley. Recovering the fibres of wool from fabrics or materials composed of wool combined with cotton or other vegetable substances.

1079. E. and F. A. Leigh. Cotton gins.

1090. E. Mitchell. Reaping and mowing machines.

1099. J. Badart. Preparation of rape seed cake, linseed cake, poppyseed cake, niger seed cake, sesseme seed cake, and ground nut cake.

1117. R. G. Kent. Shades and reflectors for gas lights.

1126. W. C. Wilkins. Lamps.

1137. A. V. Newton. Sewing machines. (A communication.)

1159. G. T. Bousfield. Steam engines. (A communication.)

1160. W. Thomson. Obtaining motive power.

1189. T. Warren. Glass and other furnaces or kilns.

1238. E. B. Wilson. Manufacture of iron and other metals.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed May 27, 1863.

3191. J. Cresswell and E. T. Greves.
3192. S. J. Browning.
3194. W. Buller and J. M. Mugford.
3196. J. Adams and W. C. White.
3197. A. Dudgeon.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office, 25, Southampton-buildings, Chancery-lane.

LIST OF DESIGNS FOR ARTICLES OF UTILITY REGISTERED.

Dates of Registration.	Nos. in Register.	Names and Addresses.	Subjects of Design.
Feb. 4,	4537	T. Woodward, Brmhm.	Pistol.
„ 10,	4538	H. W. Hart, Fleet-st...	Reflectors.
„ „	4539	J. A. Forrest and Co., Liverpool	Ventilator.
„ 12,	4540	J. Mantle, Birminghm.	Neck chain.
„ 23,	4541	A. W. Cooper, Sheffield	Dessert case.
„ 26,	4542	J. Weeks, Baker-street	Parasol.
Mar. 12,	4543	G. Clarke, Marchmont-street	Fire-escape.
„ 16,	4544	W. H. Phillips, Birmingham	Grindstone spindle.
„ 17,	4545	S. Proctor, Elsecar, Yorkshire	Casing for fire-places.
„ 26,	4546	A. Nash, Royston	Malt screen.
April 8,	4547	J. Mason, Birmingham	Fountain pen.
„ 9,	4548	R. and C. Phelps, Birmingham	Apparatus for producing frost on the stems of jewellery pins.
„ 16,	4549	A. W. Banks, Newgate-street	Bottle.
„ „	4550	W. Bacon & T. Hawley, Coventry	Scarf.
„ 23,	4551	S. Baker, Lombard-st.	Shooting boots.
„ 27,	4552	E. Banes, Newgate-st.	Scarf fastener.
„ „	4553	H. Doulton and Co., Lambeth	Boot warmer.
„ 29,	4554	Benham and Froud, Chandos-street	Jelly mould.

PROVISIONAL REGISTRATIONS.

Feb. 3,	1422	J. Weeks, Baker-street	Parasol.
„ 9,	1423	J. Stone, Hoxton	Bustle.
„ 11,	1424	W. Riddell, Birmghm.	Carving fork.
„ 12,	1425	A. W. Cooper, Sheffield	Dessert case.
„ „	1426	W. Anderson and C. Coe, K	Corner joint.

MARINE ENGINE IMPROVEMENT.

FEW things are more remarkable than the distinctive peculiarities of the different systems of propulsion which have been adopted on land and water—peculiarities which are the primary cause of the marked difference in the results obtained from the combustion of similar quantities of fuel in a locomotive and a steam-boat, and far more the result of that tentativeness with which mankind generally retain the designs, rules, and sundry directions laid down by the successful pioneers of science, than because of any particular advantages which such rules or designs hold out.

We feel little doubt that had James Watt turned his attention with any considerable energy to the construction of a locomotive, he would have succeeded in producing a very excellent machine, and one which, in the absence of anything better, would have fulfilled a very good purpose; but we feel equally certain his engine would have borne about it all the destructive attributes of that system of condensation so peculiarly his own. But James Watt did not invent the locomotive. It is difficult to say who did; but we can at all events trace the result which plays so important a part in our daily affairs to the combined exertions of several individuals, who were all more or less impressed with the conviction that the principle of condensation was totally inapplicable to such a machine, and that from steam of an excessive pressure, as compared with that employed by Watt, could any really useful result alone be expected. This conviction has led to the best results, and we cannot but think it unfortunate that the first promoters of steam navigation did not hold similar views; had they done so, it would ere now have held out advantages which up to the present it has certainly failed to do.

In a former article we endeavoured to point out some of the reasons which have led to the adoption and retention of a peculiarly heavy and cumbrous description of mechanism on board ship, the useful effect of which is extremely disproportioned, if we take a first-class locomotive as our standard, to the space occupied, and the weight and first cost of the machine. But there yet remains a reason, potent in preventing the adoption of anything lighter, which is simply the conviction almost universally held by constructive engineers, that it is impossible to obtain an excessive development of power from what they style small machines. This we admit to be true, within certain limits, which permit a latitude, of which we have been too slow to avail ourselves.

Weight and size are merely relative qualities, and have no immediate influence whatever on the efficiency of any machine whose object is to supply power; least of all, on the steam-engine, whose efficiency depends on many principles with which they have nothing to do. Whether an engine weighs ten tons or or a hundred tons, it may be equally effective and useful, provided the different parts, stationary and moving, are so proportioned as to be capable of sustaining the maximum of force which the machine is capable of evolving; and it therefore follows that the proper consideration for the engineer who has to design engines whose size and weights are limited, is the best means of reducing or rather modifying the strain. They exert, until, without reducing the development of power, they are no longer so excessive as to endanger very light machinery. This has been the guiding principle in the construction of the locomotive almost from the beginning, while it has never once been regarded in its proper light in designing the marine engine, until within the last few years. On the contrary, much has been taken for granted without experiment, because experiment has not been forced on the marine as it has been on the locomotive engineer by the pressure of circumstances. The consequence is that the capabilities of our steamships have been wasted in carrying about tons of useless iron, and, worse still, enormous quantities of coal rendered necessary by the utter disregard of scientific truths, which are now patent to all. Steamships should be something better than mere hulls to carry machinery.

Such engines as the "Lord of the Isles" or the "Great Britain" locomotives, have on many occasions exerted as much as 800 indicated horse power, in regular work. If we neglect the weights of the leading and trailing wheels, springs, &c., as being only necessary to the locomotion of the machine, not to the mere exercise of its power, we shall find that any of them weigh considerably under 40 tons in working order—that is to say, with the boiler full and the drivers retained as flywheels. Now 40 tons divided into 800-horse power, gives us 20-horse power for each ton of dead weight. If we regard 800-horse power as an abnormal effort, which, if long continued, might lead to the injury of the machine, and only consider the maximum of effect as 500-horse power we have still over 12-horse power for each ton. Now, the best practice in marine engineering has hitherto failed to reduce the weight, of direct-acting engines, with tubular boilers and injection condensers, to less than 12 cwt. per horse-power nominal; and as the indicated generally exceeds the nominal, about three times on an average, we may safely say that a ton of the marine machinery in daily use produces but 6-horse power, while a first-class locomotive can produce 12 or 15 with the greatest ease, and even 20 under exceptional circumstances; such facts speak for themselves, and ought naturally to lead to the consideration of the means of procuring equally good results in both cases: the first effect of which would be to place at our disposal a class of vessels possessing all the speed, and two or three times the cargo capacity, of the "Persia," for instance, without any increase in her size. Such vessels could not fail to prove more highly remunerative to their owners than anything which has gone before; and it is sufficiently remarkable that no trials have ever been made with steamships fitted with screw propellers and small engines of the locomotive class, running at locomotive speed with high pressure. We can only attribute this supineness to the small interest which companies generally take in mere engineering concerns—matters which they usually trust wholly to their superintending engineer, who, having all the risk in case of failure, and but little prospect of reward in case of succcess, is commonly well satisfied to do well, without any desire to risk reputation or prospects in the attempt to do better. Nevertheless, the reward held out to shipowners is magnificent, and it is high time they bestirred themselves to obtain it.

We have already observed that on the strength of its parts, the weight of the marine engine is regarded as dependent—a conclusion barely correct in a limited sense; for, after all, the weight of the moving portions of these machines, bears but a small proportion to that of the enormous cylinders rendered necessary by an absurd adherence to the use of low pressure steam, or to the excessive quantity of water carried in their boilers. An excuse might have been heretofore found for carrying about all this dead weight, in the necessity for raising steam from salt water under low pressure, but *tout cela est changé* by surface condensation, and, in consequence, the use of a pressure of 100 lb. or 150 lb. is just as practicable at sea as it has heretofore been on land, and of course in properly constructed boilers is equally safe in either case.

We cannot fail to trace the present state of the problem of marine propulsion to the very circumstances of its history. Taking its rise almost with the advent of steam-power, its introducers were neither aware of, nor regarded as necessary, any means of reducing the size of their engines. The locomotive had not yet been invented; high pressure was in this country almost unknown; the theory of the steam-engine had yet to be elaborated; and consequently they were content with the goods the god's gave them, without searching any farther. Even if they had, so long as paddles remained the sole means of propulsion, their search would have been of little avail, for while confined to their use, it would have been folly to expect any great reduction in the size or weight of the engines which put them in motion; for although the question of speed may not bear any positive relation to the production of power, yet much may depend on the means at our disposal for its subsequent utilization. Until the introduction of the screw there was no opening for high-speeded engines.

Fifty years of progress have dissipated these difficulties and obstacles. The theory of expansion, and the best means of availing ourselves of its benefits, are well understood. High-speeded engines daily prove themselves more successful, and meet with an enlarged application on land. No longer confined to the use of the comparatively clumsy paddle-wheel, we have in the screw an instrument of propulsion above all others adapted to the requirements of a class of engine which cannot fail to give as good results in our steam-boats, as it has in our factories and on our railways. The high speed at which the screw requires to be driven, is still regarded as a great defect; we, on the contrary, regard that fact as the greatest merit of the instrument. Owing to it, the use of enormous pistons moving at slow speeds, becomes a mechanical absurdity; for those principles of construction which have done such good service in the locomotive, are placed at the disposal of the marine engineer. Small cylinders and high speeds may be employed to produce any required power; expansion may be carried to its utmost limit; gearing may in many cases be dispensed with, even with small screws with a fine pitch; and these advantages, combined with surface condensation, and the high pressure placed by it our disposal, should give economical results far superior to anything hitherto attained.

We scarcely think the present style of marine boiler as being the best suited to the circumstances under which it is employed. No part of our steam-boat machinery requires re-modelling more than the means by which we generate steam; but this same question of boiler construction is too large, and opens up far too wide a field, for us to enter on it now. At another time, we may point out some of the more salient points in the construction of that class of engine which holds out the promise of the best results. In the meanwhile, we shall be happy to hear from our correspondents on a subject, which the re-modelling of our fleet renders of paramount importance. When the armour question becomes a little more settled, the question of improvement in our modes of propulsion will, we feel certain, receive much more attention than it does now. It is universally admitted that the power of obtaining high speeds, and maintaining them for long periods of time without having to run for a coaling port, will prove a matter of the most essential importance to the future success of our Navy; and as Government, wisely or not, seldom takes the initiative in such things, we could wish that our mercantile marine would, ere the demand arrives, already supply all the facts and data necessary for the universal adoption of the best means of obtaining these important ends.

GRAIN ELEVATORS.

The processes of thrashing, cleaning, and elevating grain, simple as they may seem, involve operations of such nicety that the whole subject deserves to rank as a separate science. We find on examination, that corn, like air, water, electricity, &c., requires the observance of certain fixed and determinate rules in everything connected with its management, to a degree which the uninitiated in such matters little imagine. The belief obtains that all the varying processes through which it goes, from the time it leaves the farmer's stack, until it is pronounced fit for the miller, can be performed by comparatively rude appliances, which are easily constructed, and exercise no great demand on the inventive abilities of the agricultural engineer. Never was there a greater error; and we do not hesitate to say that the construction of a good thrashing machine involves more difficulties, and requires more accurate knowledge of certain principles, than that of many other machines which are regarded as models of scientific skill properly applied; and we cannot but regard it as strange that the young engineer has not one text-book at his command which can afford him sound theoretical or practical information on this very important subject. The preparation of corn for the market is not so easy a matter now as it formerly was; farmers are no longer satisfied to send their produce to the purchaser in a partially prepared state, which involved a considerable amount of expensive labour on the part of the miller before it could be pronounced fit for the process of grinding; and the growing tendency is not only to bring samples to the highest possible state of perfection, but also to perform all the necessary operations at one time, and in a single machine. When we consider the different descriptions of grain dealt with and the varying states in which it is submitted to the action of this apparatus, we shall be better able to form an opinion of the difficulties involved. It is not our intention at present to enter on the question of the construction of thrashing machinery, but to glance at one of its appurtenances, the Elevator, which bids fair to play an important part in the future of these machines.

From the time that the first mill was built three stories high, it is more than probable that the want of a suitable means of raising corn from the lower to the upper stories made itself felt. The sturdy backs of the miller and his men supplied the want for years in a very effectual manner, we feel little doubt; but growing intelligence after a time pointed out far better means of attaining the same end, and various descriptions of sack-hoist, may still be found in mills of a good old age. The inventors of these ingenious and useful applications of power have all sunk into oblivion, and nothing remains of them but their works. Now, although the hoisting of grain in mass, or by the sack at a time, was found suitable enough to the wants of the miller, it did not by any means supply the demands of the brewer or distiller, who generally keep their corn stored in large receptacles or granaries, from which it requires to be elevated to the upper storeys of the building periodically, in very considerable quantities, quite precluding a resort to the operation of sacking.

The machine designed to fulfil this purpose bears the name of "Jacob's Ladder," and for any evidence we have to the contrary might as well have been invented by the patriarch whose name it bears as any one else. It consists of a broad endless leather belt, running over small wheels—one in the highest storey of the building; the other in the lowest is fixed in a kind of box, which can easily be placed in communication with a hopper into which corn is delivered in a continuous stream from the granaries on the ground floor. On the surface of the belt are fixed a number of tin buckets by means of rivets. Power being applied to the upper pulley, by its revolution it causes the ascent of one side of the belt and the descent of the other, when the little tin cups, dipping into the corn in the receptacle at the bottom, become partially filled with the grain, which they carry to the top and discharge into a suitable spout, on being upset in passing over the upper pulley. The machine is simple, and in such situations, where it has only clean corn to deal with works admirably; once the speed and the feed are regulated, it will, without attention and with unvarying regularity, continue to carry up corn so long as it remains in motion. As a consequence, it has met with almost universal application, and continues to enjoy high favour. Still it is quite incapable of meeting an emergency when more than the normal quantity of grain requires to be raised in a given time. If run above a certain speed the corn is tossed out of the cups, which ascend only partially filled; and although this is a matter of little importance in the regular work of a mill or brewery, in other situations it has become a defect which promises to lead to its supersedal by very different mechanism.

In the first thrashing machines introduced into this country, the inventor satisfied himself with merely extracting the grain from its straw, leaving the subsequent operation of cleaning and dressing to be accomplished by hand in other machines; but the inconvenience of this mode of proceeding soon becoming evident, led to the combination of the dressing, with the thrashing machinery; and as this last always delivers the corn near the ground in the first instance, owing to its working conditions, it became necessary to elevate the thrashed grain to the top of the machine, in order that it might find its way through the dressing apparatus to the sack. The Jacob's Ladder offered the readiest means of attaining this end, and was immediately employed; but it soon proved itself sadly deficient in supplying the demands of the farmer, who could ill brook the frequent stoppage of the machine—a result which constantly took place in consequence of the admixture of considerable quantities of short straw with the corn, which choked up the buckets, got wound on the pulley shafts and filled up the wooden case in which the elevator generally worked. Worst of all, it was frequently found incapable of raising the extra quantities of grain, thrashed from peculiarly productive samples; nevertheless, it remained in general use until three or four years ago, when another Elevator was brought into notice by Messrs. Bruckshaw and Underhill.

One of the most necessary processes which barley, &c., undergoes in its preparation for market, is the removal of the beard or awn. This has hitherto been performed by a machine called a "hummeler" which is simply a horizontal iron tube about 9 in. in diameter and 5 or 6 ft. long, containing a spindle set round with a great number of small blunt knives, which being arranged spirally, force the corn poured in at one end by the elevator, towards the other end, from which it falls on the dressing sieves, the spindle revolving at three or four hundred revolutions per minute. The knives effectually remove the beard or awn, and brighten and improve the general appearance of any corn, bearded or not, which passes through the apparatus. Mr. Underhill accomplishes both the hummeling and elevating of the grain in one operation, by the following means:—

In any convenient situation at the bottom of the thrashing machine, he arranges a fan, very similar to those employed in blowing cupolas and smithy fires. It is usually about 30 in. in diameter fitted with straight vanes, made of stout sheet-iron with the sides turned up about ½ in. These vanes are about 8 in. long and 4 in. wide, and are riveted to stout wrought-iron arms forged with the centre boss in one piece. The fan-case is of cast and wrought iron, only just wide enough to permit the fan to revolve within without touching it; from the circumference of the case above the centre proceeds a tangential inclined wind-trunk, about 8 in. wide by 4 in. deep. The upper end of this trunk opens into a box of peculiar but simple construction, which permits the escape of air, but not of grain. The fan being caused to make about 700 revolutions per minute, sends a powerful current of air up the trunk, while the thrashed corn poured into the bottom of the fan-case by a suitable spout is, by the combined stroke of the fan-blades and the powerful current of air, carried in almost any quantity to the top of the machine, or indeed much higher: the patentees stating that it will elevate 30 ft. with ease.

The action of the fan effectually removes every particle of awn from the corn; indeed, it occasionally does much more, breaking the the grain in a very objectionable manner—a result always due to improper fitting and arrangements, easily avoided by those conversant with the peculiarities of the apparatus. Thus we have known it break corn at 700 revolutions, while it did not injure it in the slightest degree at 1,200 revolutions per minute—a result we attribute to the fact of the corn being elevated rather by the current of air, than the stroke of the fan. In some cases a difficulty is found in finding a suitable place for it on machines not specially intended for its application—a difficulty often got over by taking the wind-trunk from some part of the circumference of the fan-case below, instead of above the centre, which permits the revolution of the fan in an opposite direction. The powerful blast aids materially in carrying off the chaff and dirt, and the machine has hitherto proved itself extremely efficient and satisfactory.

Messrs. Smith and Higgs have introduced an Elevator, whose action depends on nearly the same principles as those which regulate the ascent of water in a pump. Although it has not yet received much attention, being of very recent invention, we believe it may yet be capable of supplying all the requirements which may entitle it to be called a very excellent machine. A fan something similar to that last described, but having peculiarly curved vanes, is mounted on the drum shaft of the thrashing machine. A flat trunk, the opening through which is about 15 in. long and 2 in. wide, proceeds from the centre of the closed fan-case to the lower part of the machine, where it ends in a kind of mouth-piece just over a shallow iron tray, into which the thrashed corn is delivered. The fan runs about 900 revolutions per minute. The word "suck" is neither elegant nor scientifically accurate, yet we can find nothing which better expresses our meaning, for the corn is actually "sucked" up from the tray through the trunk into the fan, from which it is propelled through a second trunk, fixed horizontally, or nearly so, above the dressing machinery, while the air, leaving the corn to make its way through this apparatus, passes down a large tube, and acts the part of first winnower to the rough grain.

The elevating of grain in quantity by this machine depends on many of those nice points of scientific detail, which we have already stated to be largely involved in the construction of thrashing and dressing machinery. The exact curve of the fan-blades, the shape of the elevating trunk, the curve by which it communicates with the interior of the fan-case—all exert a powerful influence on its action. There seems to be little limit to the height to which it will elevate corn; we believe it equal to Underhill's in this respect, and with suitable arrangements it will dress the corn equally well. Curiously enough, three different individuals, each without the knowledge of the others, applied for provisional protection for this invention within a fortnight—a remarkable instance of a similar want giving rise to a similar train of ideas in distinct individuals at the same time.

Messrs. Hornsby, preferring to retain the old-fashioned Jacob's Ladder, yet fully alive to all its defects, have succeeded in so far remodelling it as to construct a very efficient Elevator. Removing the buckets, they have replaced them with flat iron plates, standing at right angles to the surface of the belt, which runs at the upper end on a pulley on the chain shaft, and below on a second pulley, situated within the case, which resembles that usually employed, except that it is lined with roughened iron plates. The corn is delivered into the case at the bottom, and is scraped, so to speak, up the case by the exceedingly rapid motion of the ascending plates on the belt, effectually hummeling it during the process. The belt certainly seems exposed to a considerable amount of wear, but this need not be excessive, provided the pulleys are of fair diameter; and it must be remembered that Underhill's Elevator requires a belt running at a very high speed to drive it; besides, both it and Smith's Elevator require considerable power to drive the fans, in addition to that employed in raising the corn, so that the advantages and disadvantages are pretty well divided amongst them.

The four machines, which we have now slightly described, play an important though indirect part in the preparation of our breadstuffs; and two of them, at least, involve nice questions in dynamics, which make them well worthy of the attention of those interested in such matters. There is still room for considerable improvement, especially in the reduction of the power required to work them. As to their comparative merits, we may say that, although the general principles of construction are the same in all thrashing machines, yet the means of applying them to the object in view are so various that the different forms of this class of machinery are almost endless, and of course the best results can only be obtained by selecting that description of elevator which is most suitable to the form of the machine to which it is to be applied. Not only is there often a practical difficulty in getting the grain to the elevator, but also in getting it away again, and that which might suit one form of machine admirably, might be just as unfitted for another.

HEAT AS A MODE OF MOTION.*

When Sir Isaac Newton enunciated, in his *Principia*, the first axiom or law of motion, by which he proved the indestructibility of force as applied to matter, the illustrious philosopher could scarcely then hope that his axiom would be also brought to bear upon the imponderable agencies of nature. Such, however, is the case; and the doctrine of the conservation of force, through all its transformations, is one of the most pregnant scientific theories of the age.

It could not have long escaped the attention of modern philosophers that the forces of nature are related; that heat could be produced from mechanical action, by means of compression, concussion, or friction. Galvani showed that electricity can be evolved from chemical action; Oersted, that magnetism is developed from electricity. The next step was the perception that—given any two natural forces, either of the two could be evolved from the development of the other. Thus, it was soon found that electricity could break the bonds of chemical union, after being itself evolved from chemical action; and Faraday's discovery of magneto-electricity was the inverse discovery to that of electro-magnetism by Oersted. As Mr. Joule showed in his Paper "On the Heat evolved during the Electrolysis of Water"—"the magneto-electrical machine enables us to convert mechanical power into heat, by means of the electric currents which are induced by it;" and *vice versâ*, that the mechanical power of the electro-magnetic engine is obtained by means of the heat due to the necessary chemical reactions.

It now remained to be proved that these forces were definitely related; that their interdependent reagencies could be expressed by definite numbers; that the science of thermal dynamics could be brought under the dominion of mathematical science, the great goal towards which all real knowledge must tend. Faraday's great discovery of the definite chemical effect of the voltaic current was a step in this direction; and the mechanical equivalents of heat, electricity, magnetism, and chemical action have been at last discovered. We thus not merely know that these forces can do a certain amount of mechanical work, but we also know their separate mechanical equivalents. In the words of Rankine: "As these laws have now been exactly ascertained by experiment, it must be borne in mind that their certainty is in no way dependent on the truth of the hypothesis—the probability of the hypothesis being, on the contrary, dependent on the truth of the laws."

The mechanical theory of heat is based upon the assumption that the atoms and masses of matter, throughout the universe, are steeped in an all-pervading, highly-elastic medium. This boundless sea of "ether" fills all space, connecting atom with atom, and world with world. The universe is supposed to be steeped in this infinitely elastic fluid, just as the spaces of a wetted sponge are filled with water. The force of cohesion keeps the atoms of solid bodies together, but these atoms are supposed to vibrate to and fro across a fixed position, and these oscillations are communicated through the interatomic spaces to the ether in which the ultimate particles swing. The vibrations increase in amplitude, the greater the amount of heat we impart to the body; either directly, or by the application of mechanical action, in the shape of percussion, compression, or friction. Cohesion and heat are thus the two great antagonistic principles from which depend the molecular aggregation of the substances composing the universe. In a solid substance like ice, for instance, cohesion predominates; but the communication of heat will push the particles more widely apart; and the cohesion being weakened by increasing the distance between the particles, the atoms not merely vibrate to and fro across fixed positions, but, at last, can also glide round one another. We thus have the liquid, water. Increase still further the increment of heat—the last fetters of cohesion are broken, and the former solid substance is translated into the gaseous form.

It is indifferent how the vibrations of the body are increased; whether directly by heat itself or by mechanical action. Thus, the old sailor's tradition is correct, that the sea is warmed by a storm; the mechanical dash of the billows is converted into heat. The temperature of the water of the cataract of Niagara also gets somewhat raised by the time the liquid reaches the bottom. Sir Humphry Davy states:—"I procured two parallelopipedons of ice, of the temperature of 29 deg., 6 in. long, 2 in. wide, and two-thirds of an inch thick—they were fastened by wires to two bars of iron. By a peculiar mechanism, their surfaces were placed in contact, and kept in a continued and most violent friction for some minutes. They were almost entirely converted into water, which water was collected, and its temperature ascertained to be 35 deg., after remaining in an atmosphere of a lower temperature for some minutes. The fusion only took place at the plane of contact of the two pieces of ice, and no bodies were in friction but ice." In the course of some striking experiments, Professor Tyndall partially liquified ice by means of pressure. In a famous Paper, read before the Royal Society in 1798 and reprinted in the Professor's works, Count Rumford showed that he had caused water to boil by the application of friction. A bullet, in its passage through the air, is warmed by the friction, and its concussion against the target often causes the projectile to be hissing hot. Mr. Fairbairn informed Professor Tyndall that "in the experiments at Shoeburyness it is a common thing to see a flash of light, even in broad day, when the ball strikes the target." The movement of the ball is thus transformed into molecular motion, and the impulse given by the powder reappears again in the shape of heat, and, perhaps, chemical action. Now, it is impossible to explain any of these phenomena by the caloric theory, which is founded on the supposition of the material nature of heat. Dr. Mueller, in his excellent and well-known work on Natural Philosophy, after citing several instances in which heat is produced by means of friction, declares that there is no explanation of this phenomenon by the use of the caloric theory. As was well remarked by Seguin, in 1839, the ordinary theory leads to the absurd conclusion that a finite quantity of heat produces an indefinite amount of mechanical action; a theory which accepts the possibility of a perpetual motion, which is, of itself a *reductio ad absurdum*. All modern science acknowledges the principle that we cannot, by any combination of forces or matter, produce either force or matter out of nothing. Several other anomalies and contradictions were involved in the use of the old caloric and emission theories. As is well known, different bodies have different capacities for heat. Thus, to raise a pound of water 1 deg. would require thirty times the amount of heat necessary to raise a pound of mercury 1 deg.; *vice versâ*, a pound of water in falling 1 deg. would give up thirty times more heat than mercury; and the "specific" heats of these two fluids would be represented by the numbers 1·00 and 0·0333 respectively. The caloric theory explained this difference by supposing that some substances contained more heat than others. The mechanical theory of heat gives a more rational reason for this difference. Heat being mechanical action, the reason that some bodies require more heat to raise their temperatures is, that a greater amount of *interior work* must be performed in order to drive their ultimate particles asunder. In cooling, the heat consumed in forcing the atoms wider apart is restored by their contraction. "The energy of the forces engaged in this atomic action and *interior work*, as measured by any ordinary mechanical standard, is enormous." "Gravity almost vanishes in comparison with these molecular forces." Thus, water expands on both sides of 4 deg. Centigrade or 39 deg. Fahrenheit; at 4 deg. C. it has its maximum density. "Suppose a pound of water heated from 3½ deg. C. to 4½ deg. C.—that is, 1 deg.—its volume at both temperatures is the same; there has been no forcing asunder whatever of the atomic centres, and still, though the volume is unchanged, an amount of heat has been imparted to the water, sufficient, if mechanically applied, to raise a weight of 1,390 lb. a foot high."

---

* Heat as a Mode of Motion; being a Course of Twelve Lectures delivered at the Royal Institution. By John Tyndall, F.R.S. London: Longman and Co. 1863.

The caloric or materialistic theory is particularly illogical when it attempts to explain the phenomena which accompany changes in the state of aggregation of bodies. The heat that disappears in changing the state of a body from the solid to the fluid and gaseous stages, was supposed to hide itself in some unknown manner in the intermediate spaces of the fluid or vapour. It was termed "latent" heat. According to the *mechanical* theory, the heat expended in changing the state of aggregation of bodies is "virtually the lifting of a weight," and is consumed in conferring potential energy upon the ultimate atoms. In order to make this action clearly understood, we might draw an analogy between this action of heat, and effect produced by gunpowder in driving a shot from a rifled gun. A portion of the powder is expended in giving a forward motion to the shot; another portion is consumed to produce the rotary motion of the projectile.

An amount of heat sufficient to raise the temperature of water by 1 deg. of Fahrenheit's thermometer, requires for its production 772 foot-pounds of mechanical power. The expenditure of the same amount of power will also raise 1 lb. of water to 1 deg. Fahr. This "dynamical specific heat of water" is known by the name of "Joule's equivalent," having been first determined by that gentleman through a series of experimental researches extending over many years. (772 foot-pounds being the mechanical equivalent for 1 deg. Fahr.; 1,390 foot-pounds is the equivalent for 1 deg. Centigrade.)

In a most interesting and striking manner, Professor Tyndall traces the existence of water through its various stages. 1 lb. of hydrogen, in combining with 8 lb. of oxygen, to form water, will raise 34,000 lb. of water 1 deg. C. "Knowing the number of foot-pounds corresponding to the heating of 1 lb. of water 1 deg. C., we can readily calculate the number of foot-pounds equivalent to the heating of 34,000 lb. of water 1 deg. C. Multiplying the latter number by 1,390, we find that the concussion of our 1 lb. of hydrogen with 8 lb. of oxygen is equal, in mechanical value, to the raising of 47,000,000 lb. 1 ft. high!" When this combination is effected, the substance is in the state of vapour; it first sinks to 212 deg. Fahr., and is afterwards condensed into water. The atoms of oxygen and hydrogen clash together and form the compound substance, steam; and molecules of the steam then fall together and form the liquid, water. The mechanical value of these acts can be also calculated. Thus, "9 lb. of steam in falling to water, generate an amount of heat sufficient to raise $967 \times 9 = 8{,}703$ lb. of water 1 deg. Fahr.; multiplying this number by 772, we have a product of 6,718,716 foot-pounds as the mechanical value of the mere act of condensation. The next great fall of our 9 lb. of water is from the state of liquid to that of ice, and the mechanical value of this act is equal to 993,564 foot-pounds. Thus, our 9 lb. of water, in its origin and progress, falls down three great precipices: the first fall is equivalent to the descent of a ton weight urged by gravity down a precipice 22,320 ft. high; the second fall is equal to that of a ton down a precipice 2,900 ft. high; and the third is equal to the descent of a ton down a precipice 433 ft. high."

We are now naturally led to inquire the names of the men who achieved the most in effecting this great and revolutionary progress in modern science. The history of most great discoveries, or even of the humbler inventions in trade, show how difficult it is to adjudge the palm of merit. There are several claimants to the major part of the glory. Professor Tyndall ascribes the principal honour to Dr. Mayer, of Heilbronn; M. Seguin claims it for his uncle Montgolfier, as is evidenced in a letter we published in our number for January 30th (page 78). Mr. Grove and Mr. Joule both claim the exclusive honour of the discovery. It appears to us that this discovery, like many others, has been evolved from the labours of several men working during many years; and it has been evidently long ago dimly sighted by several who have been raised by genius above their fellows. The practical connection of heat with motion must have been perceived from time immemorial; savages procure fire by the friction of two pieces of wood, and civilized men by the concussions of flint and steel. "In the common flint and steel the particles of the metal struck off are so much heated by the collision that they take fire and burn in the air."

It may be said that three great steps have led to a full explanation of this phenomenon, and justice will be best done by apportioning the honour due to the advance of each separate gradation. The original step was made by those who first conceived the idea of heat as a mode of motion. A dim glimpse of the connection of heat and mechanical force was already formed by Aristotle. Remarkable passages from Bacon are cited by Professor Tyndall, showing that Bacon rejected the idea of caloric as a material substance. Almost every advance we make in science thus adds strength to the well-known and beautiful comparison by the poet Cowley between Lord Bacon and the Prophet of Israel standing on Mount Pisgah.

As we approach our own times, the previously dim glimpses of truth get more vivid. We thus find Locke writing two centuries ago:—"Heat is a very brisk agitation of the insensible parts of the object, which produces in us that sensation from whence we denominate the object hot; so that what in our sensation is *heat*, in the object is nothing but motion."

The second great step was taken by Rumford and Davy, who distinctly proved by experiment that heat was developed by friction. Professor Tyndall reprints, as an Appendix to his second lecture, "A Paper by Count Rumford, read before the Royal Society in 1798, entitled 'An Enquiry concerning the Source of the Heat which is excited by Friction.'" Count Rumford says:—"It appears to me to be extremely difficult, if not quite impossible, to form any distinct idea of anything capable of being excited and communicated in those experiments, except it be *motion*." We refer our readers to our number of January 30th for an exposition of M. Seguin's claims. Mr. Grove appears to have systematized the previously loose and isolated conceptions as to the law of mutual convertibility. In the preface to his last edition of his "Correlation of the Physical Forces," he claims to have expounded this law in January, 1842.

The *mechanical equivalent* of heat was determined by Mayer, of Heilbronn, and Joule, of Manchester, and the last and most important step was thus taken towards the formation of the science of thermo-dynamics. Mayer determined, by calculation, the mechanical equivalent of heat from the velocity of sound in air, and he published his paper in 1842. By experimental means, and completely independent of Mayer's researches, Mr. Joule also determined the mechanical equivalent of heat. Mr. Joule showed the elevation of temperature caused by the revolution of paddles in a suitable vessel filled with water, as also with mercury and sperm oil; he measured the heat evolved from the friction of cast-iron discs against each other, and also the heat produced by forcing water through capillary tubes. By these experiments he was enabled to determine the mechanical equivalent of heat. We are thus almost wholly indebted to Mr. Joule for the experimental researches which have led to the present position of the question. Since Joule's determination of the mechanical equivalent of heat, the subject has been mathematically investigated by Clausius, Helmholtz, Holtzmann, Kirchhoff, Rankine, and Thomson. It remains to be seen who will first practically apply the new philosophy; that many applications are possible, we have no doubt. As Joule remarks: the new principles "lead to a theory of the steam-engine very different to the one generally received, but at the same time much more accordant with facts. From them we may infer that the steam, while expanding in the cylinder, loses heat in quantity exactly proportional to the mechanical force which it communicates by means of the piston, and that on the condensation of the steam, the heat thus converted is *not* given back. Supposing no loss of heat by radiation, &c., the theory here advanced demands that the heat given out in the condenser shall be less than that communicated to the boiler from the furnace, in exact proportion to the equivalent of mechanical power developed." The enormous consumption of power by means of friction can be explained upon no other hypothesis than that of "Mechanical effect = Heat." The mere rubbing effect of two rough surfaces against each other, the mere catching of the prominences of one surface by those of the other, are not causes sufficiently powerful to account for the almost instantaneous consumption of power by friction. When the breaks are applied to a railway train, a winding engine, &c., the power of the steam is mainly reconverted into heat.

New and revolutionary theories like the one we are alluding to have a disturbing influence on many men's minds. They effect changes in our old ways of looking at the things passing daily before our eyes, and they cause revolutions in our ordinary views too fundamental and startling to be quite pleasant. That original thinker and observer, Archbishop Whately, has well noticed that the common love of mankind for novelty affects only details; new systems in science have attractions for only a select few, while they disturb the minds of the many.

Professor Tyndall uses alternately and indifferently the scale of Fahrenheit, and that of Celsius or the Centigrade thermometric scale. In some cases this is liable to lead to a little perplexity on the part of the reader. It is unfortunate that the absurd scale of Fahrenheit cannot be entirely banished from our scientific works. Founded on the wrong assumption that the zero corresponded with the total absence of heat, its use is an anomaly in the present state of science; while the inapplicability of its numbers to the decimal notation, often causes a serious loss of time.

A want has long been felt amongst engineers for a clear and intelligible work on the mechanical theory of heat, and which would, at the same time, give an account of the scope of the experiments, and numerical data upon which the theory is founded. This want is now supplied by Professor Tyndall's book. The clear style of the work adapts it to the most ordinary capacities; and the reader is raised to "the level of these questions from a basis so elementary, that a person possessing any imaginative faculty and power of concentration" can easily follow the subject. The engravings are also well chosen, and excellent in execution, while they completely carry out their true purpose—that of fully illustrating the context. With the exception of a short portion of Lecture IX. in Mr. Fairbairn's work, "Useful Information for Engineers," this book of Professor Tyndall is the only popular exposition of thermal dynamics. Popular as it is, however, we are nevertheless convinced that the most accomplished man of science would rise from the perusal of this book with an additional amount of information.

VAILE'S PROPELLER.*

That man would be rash who asserted that we had arrived at the best means of propelling vessels. Neither paddle nor screw can be considered as doing more than approaching towards that theoretical perfection which our greatest engineers have searched after since the days of Symington or Fulton. We feel disposed, then, to look favourably on every attempt made to improve our existing systems, convinced as we are that the whole subject of steam navigation is as yet in its infancy.

Mr. Vaile's propeller comes late on the field, as compared with paddles or screws—a fact which must militate seriously against its general adoption, apart from every other consideration. This is to be regretted, as the principle on which it is constructed seems theoretically right, which is more than the warmest advocates of other systems can assert. And those matters of practical detail, which will doubtless be found difficulties—but not, we imagine, insurmountable ones—will in consequence be regarded as being of far more importance, than if the three modes of propulsion, paddle, screw, and Mr. Vaile's, had all started in the race for public favour at the same time.

The greatest objection hitherto urged against propellers of this kind has been the wear of the chains. This we regard as a mere matter of constructive detail. If the chains are made correctly on scientific principles, with case-hardened eyes, steel pins, and a sufficiently large bearing surface where the links take the cogs, so to speak, of the chain wheels, the wear will be found very trifling. We have used chains on somewhat similar wheels in traction engines ere now, where they have for miles at a time been exposed to a strain of 15 or 20 tons, the chain running at about two miles per hour, without either jerk or perceptible wear. On one occasion, with a new chain, with link pins at every 8 in., and much more roughly made than Mr. Vaile's arrangement of jointed rods would be, we found the chain stretch half an inch in a journey of 120 miles, and this was solely due to the chain coming to a bearing in the first 20 miles.

For various reasons which we cannot enter on very fully, we fear Mr. Vaile's propeller will never prove very suitable for oceanic navigation. The fact of two shafts being necessary, and the complication of the whole machine, must, we think prevent its coming into favour, under circumstances which have excluded the feathering paddle-wheel. Ice, on the North American routes, frequently demolishes half the float boards, and even twists the wheel arms, of our trans-Atlantic steamers, and has indeed proved so mischievous, that the feathering wheel has fallen into complete disfavour for these boats.

But Mr. Vaile has, in our opinion, a field open to him quite large enough to afford fame and fortune. We consider his propeller eminently adapted to the exigencies of river navigation. The shallow water in which it will work, the powerful hold which it can take of the water when ascending currents, the small height of its centre of gravity, are all advantages which must tell on engineering opinion. The rivers of our Indian possessions offer a fair opening, and we think Mr. Vaile would do well to turn his attention to the introduction of his invention in that quarter.

The little pamphlet before us is written well, and as impartially as anything of the kind can be, and is certainly an able exposition of a system which bears strong evidence of intrinsic merit.

LIGHTHOUSES AND ELECTRICITY.

The bump of caution is largely developed in the heads of the members of the Trinity House, developed, indeed, to a degree which we only find equalled in the craniums of the honourable members of the Board of Trade. It is now some time since these gentlemen were afforded a fair opportunity of displaying the effects of this bump; and we feel little doubt that the comparatively recent attempts which have been made to introduce the electric light, as a substitute for oil lamps in our lighthouses, have been hailed by them as an opportunity of displaying that devotion to economy for which they have been so justly celebrated. Indeed, were a feasible plan laid before these gentlemen whereby the sun could be compelled to remain above the horizon the twenty-four hours through, as he does for six months of the year in high latitudes, we have every reason to conclude that they would still adhere to the use of oil lamps and parabolic reflectors, as far superior means of showing a ship her whereabouts.

Lord Lovaine addressed the House of Commons on this important subject on Friday last. Mr. M. Gibson's reply is a model for all legislators who are asked questions they feel no desire to reply to. It might have meant anything; it did mean nothing; caution is necessary, is a virtue when properly exercised, but becomes one of the worst of faults, in a public body, when overdone. The electric light has for nine months proved itself at Dungeness superior to any other light ever introduced as an aid to navigation. Mr. M. Gibson regards this as "a very promising experiment," nothing more.

England is generally considered to possess the most valuable navies, warlike and mercantile, in the world; we also possess, unfortunately, as dangerous shores as can anywhere else be found, within the compass of the few hundred miles which are able to girdle our island. Our wrecks, alas! can be counted each year by the hundred. The misery involved thereby no man can count; yet in the darkest night, on the most treacherous shore, the hardy mariner deems himself safe, if he can but see and recognise the well-known light which is to him a beacon of safety. The finger of science points out the most powerful light yet known, as being ready to our purpose—a light distinguishable from all others, ruling paramount over storm and mist, resembling nothing but the bright sun in noon day in its character. Experience has tested and proved its value month after month; but caution and parsimony interfere; and for the sake of a little gold, we refuse to avail ourselves of the greatest benefit which science has yet held out to the sailor. The receipts from lighthouse dues already exceed the expenses of their maintenance to an amount which might, perhaps, supply sufficient funds, not only to fit up every structure of the kind on our coast with the electric apparatus, but also to permit the adoption of arrangements which would allow of the immediate substitution of the ordinary lamp in case of the accidental failure of the new system.

During the nine months that this light, and the machinery necessary for its production, were tested at Dungeness, it became extinguished but once for 2 minutes, once for 30 seconds, and on 18 other occasions for shorter periods of time, during the hours at which it should have been alight; and this, be it remembered, under the supervision of attendants so careless, that on several occasions they nearly permitted the steam boilers to explode. Mr. Holmes' system cannot be called untried or unsuccessful after such an experiment.

As to the quality of the light, it is unnecessary to speak; the greatest opponents to its use, on other grounds, admit that, as a light, it is superior to anything which has gone before. Of its ultimate universal introduction we feel little doubt; but under the present "cautious" system, we much fear that many stormy winters will elapse before that desirable end is attained. A heavy responsibility rests on those who have the means of introducing another element of safety in all that concerns our home navigation, and yet hesitate to do so, from that supineness and parsimony, improperly called caution.

STREET RAILWAY BRIDGES.

The distinguishing characteristic of modern engineering works is unmitigated ugliness. The fact is patent to every one. The goddess of taste has flown. Venus and Vulcan separated from incompatibility of disposition hundreds of years ago, and do not seem likely to become better friends in this matter-of-fact age of ours.

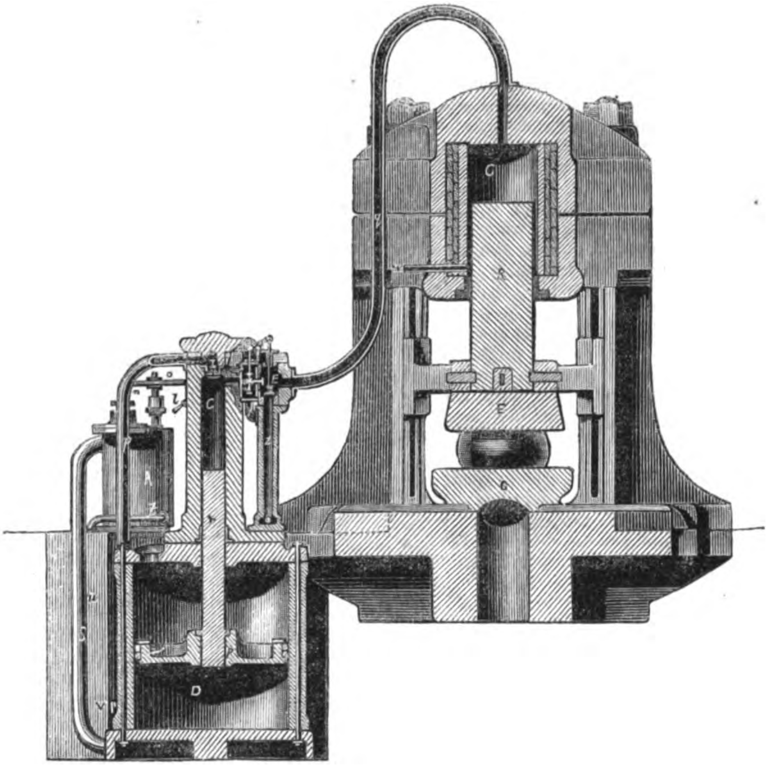
The extension of railway communication through the metropolis opens a new field for street architecture. Bridges of all forms are likely to span our leading thoroughfares, and might, for anything we can see to the contrary, be made "things of beauty," if not "joys for ever." But the specimens we are already favoured with are anything but encouraging. Witness the new tunnel at Southwark-road. Perhaps, hereafter, these things will be profusely decorated. Paint is cheap; a ton of cast-iron moulding and trellis-work is very inexpensive and easily applied, with, we apprehend, the result of making that which is already bad very much worse. A magnificent gilded frame would scarcely place a public-house sign-board on a par with a Titian or a Murillo. We want beauty of form, not meretricious decoration.

It is urged, with some show of reason, that it is difficult to construct a very short bridge which shall be handsome. The same objection has, seemingly, applied with considerable force to

---

* Vaile's Patent Endless Chain Propeller, for the more Rapid and Economical Propulsion of Ships. By Robert Vaile. London: Saville and Edwards. 1863.

SHANKS AND KOHN'S HYDROSTATIC PRESS.



some of our long ones; but the colossal size of some of these works, conveys an idea of sublimity to the mind which makes us forget their ugliness. Unfortunately, this does not apply to bridges of 60 ft. or 70 ft. span; and, without much careful designing, such structures are likely to be very useful, perhaps, but very hideous as well.

A correspondent of one of the daily papers suggests that an open-work foot-bridge might be carried across the street at each side of the main girders which support the railway. The idea is a good one, and would, if well developed, give a lightness of appearance to such bridges which would add materially to their beauty, and these foot-ways would, besides, supply a want generally felt in crowded parts of the town—such as Ludgate-hill. The extra cost would be very trifling, not much more, perhaps, than that of scrolls and false panels, which, though they may decorate, cannot beautify.

SHANKS AND KOHN'S HYDROSTATIC PRESS.

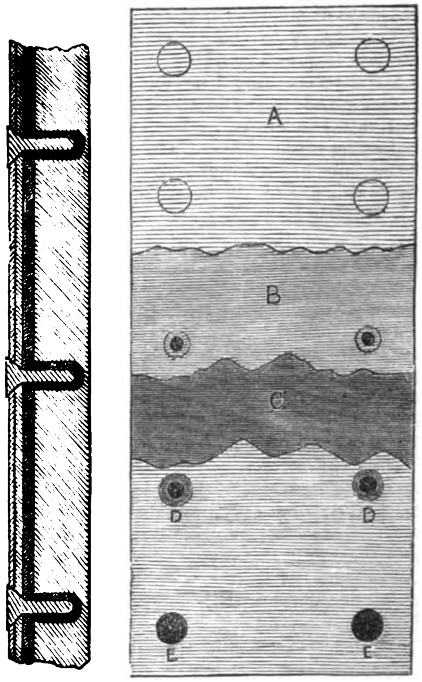
The improved hydrostatic press illustrated in section in the accompanying engraving, has been recently patented by Messrs. Shanks and Kohn, of Robert-street, Adelphi.

The improvement consists in working a hydrostatic press by steam power in such a manner as to exert the direct pressure of the steam upon the water in the main cylinder of the press by opening a free communication between the cylinder and the boiler, and move the ram by the direct pressure until the resistance of the object operated upon be equal to the pressure, at which moment steam is admitted under a large piston operating on a ram of smaller diameter in communication with the main ram, so that the motion of the lesser ram produces on the lesser one an increased pressure in the ratio of their respective areas.

The press cylinder C is mounted on standards. The ram R carries the face or upper mould F, and the anvil or lower mould G is made to slide on the sole plate so as to be drawn from under the upper mould to a convenient distance for receiving the article from the frame, and afterwards to be returned to its central position to be operated upon. A is a vessel connected by a pipe with the steam space, and by a second pipe with the water space of the boiler; a slide valve worked by a wheel *o*, or any other suitable arrangement, being provided for opening and shutting off the communication. A pipe *p* leads from the bottom of the said vessel A to the space *c*, which communicates with the main cylinder of the press C by the pipe *q*. The ram of the press cylinder R has at its upper end a piston packed on both sides; and a third packing is applied against the ram at the bottom of the press cylinder. An annular space is formed under the piston of the ram R, which is brought into direct communication with the water in the boiler by the pipes *t*, *v*, and *w*, leading through the vessel *u* and the valve *x*. The upper part of the vessel A contains a weighted valve *n*, which, when lifted by the steam pressure, admits the steam through the pipe *s* under the piston of the large steam cylinder D, which is connected to the small hydraulic ram *r*. The valves E and *x* can by means of levers be made to open a communication between the press cylinder above and below the piston and the water reservoir, open to the atmosphere, through the pipes *y* and *z*; but during the action of pressing these valves are closed.

For bringing the press into action, the valve *o* is opened, and the communication between the boiler and the vessel A established. The water from the bottom of the vessel will be forced through the pipes *p* and *q* into the main cylinder of the press, and exert a pressure on the ram R proportionate to the pressure in the boiler. The communication between the boiler and annular space under the piston of the ram R being also established, the ram will be forced down with a pressure corresponding to the difference of the sectional areas of the whole piston and the said annular space; this direct action will continue so long as the resistance to the descent of the ram is less than the pressure on the weighted valve *n*, but as soon as this pressure is arrived at, the steam will lift the valve, and get access to the piston in the large cylinder D. The total steam pressure on the piston P will thereby be transmitted to the ram *r*, and this will exert upon the main ram R a further downward pressure in proportion to the respective areas of the two rams. By closing the valve *o*, the exhaust passage of the steam cylinder D is opened, and the pressure upon the ram R is relieved; the boiler pressure maintained under the piston of the said ram forces it upwards so long as the water from the main cylinder can follow the ram *r* in its descent. By these means the two moulds of the press are made to approach each other to a definite distance, each stroke regulated by the quantity of water between the two rams R and *r*. For raising and lowering the ram R without exerting pressure, valves E and *x* are provided. The opening of E causes the escape of water from the cylinder and the ascent of the ram by the upward pressure against the piston. The valve *x* when placed in the position shown allows the ram to descend by its own weight, and to draw water from the reservoir into the press cylinder.

MUNTZ'S PATENT SHEATHING FOR IRON SHIPS.



In our last number we mentioned that a specimen of this sheathing had been exhibited at the *conversazione* of the Society of Civil Engineers: we now append a drawing of the invention.

When Muntz's patent metal is applied to iron ships, it is necessary that it should be perfectly insulated, which is done under this patent by placing sheets of india rubber or ebonite between the metal and the ship.

The nails for attaching the sheathing to the iron ship must also be insulated; and small holes, about ½ in. diameter and ¾ in. deep, are drilled in the iron of the ship, to correspond with holes in the sheathing; and in these holes plugs of ebonite are driven, which receive the nails and completely insulate them from the iron of the ship. (*See drawing.*)

The shortness of the nail may be objected to; but experience has shown that a nail ¾ of an inch in length, driven into the ebonite plug, supported as it is by iron, requires a greater strain to draw it than a 1½ in. nail driven into oak.

The drawing will, we think, illustrate the subject sufficiently without further description.

CHEMISTRY OF STEEL.

A continuation of M. Caron's[*] researches on this subject relates to the function performed by manganese in the production of steel. Regarding it as a fact that all good steel is obtained from spathic or hematite ores highly impregnated with manganese, and assuming that the presence of this metal is almost essential to the production of steel, he has endeavoured to ascertain the nature of its influence. He states that, by means of a suitable addition of metallic manganese, pig iron may be deprived of the sulphur and silicium it contains, but that no influence is exercised in the eparation of phosphorus.

---

[*] *Comptes-Rendus*, lvi., 828.

The pig iron with which he experimented is described as of very good quality, containing only traces of silicium, and it was melted by means of wood charcoal as free as possible from phosphorus, sulphur, and silicium.

One portion of this pig iron was melted with a known quantity of iron phosphide; another portion, with iron sulphide; and a third, with iron silicide. The three kinds of iron thus obtained were the subject of the experiments.

Two equal quantities of the phosphuretted iron were melted in crucibles; in the one instance without any addition, in the other instance with 6 per cent. of metallic manganese. The manganese used gave on analysis:—

Iron	1.0	100
Carbon	5.5	
Silicium	0·5	
Manganese	93.0	

The metal was kept in fushion for one hour, and then poured out. During the operation the metal was slightly decarbonized by the oxidising action of atmospheric air. Analysis of these two portions of iron gave the following percentage results:—

	Phosphorus.	Manganese.
Phosphuretted iron	0·83	
No. 1 Phosphuretted iron melted alone	0·82	
No. 2 Phosphuretted iron melted with 6 per cent. manganese	0·80	4·58
No. 1 Melted again without addition	0·79	
No. 2 Melted again without addition	0·78	3·74
No. 1 Melted a third time without addition	0·78	
No. 2 Melted a third time without addition	0·76	1·62
Phosphuretted iron melted with 10 per cent. iron oxide	0·76	
Phosphuretted iron melted with 10 per cent. iron oxide and 6 per cent. manganese	0·74	1·37

These results appear to indicate that, in refining phosphuretted pig iron, manganese does not effect the separation of phosphorus.

	Sulphur.	Manganese.
Sulphuretted iron	1·15	
No. 1 Sulphuretted iron melted alone	1·14	
No. 2 Sulphuretted iron melted with 6 per cent. manganese	1·15	3·92
No. 1 Melted again without addition	1·09	
No. 2 Melted again without addition	0·10	2·81
No. 1 Melted a third time ,, ,,	0·96	
No. 2 Melted a third time ,, ,,	0·08	1·73
Sulphuretted iron melted with 10 per cent. iron oxide	1·08	
Sulphuretted iron melted with 10 per cent. iron oxide and 6 per cent. manganese	0·07	1·22

These results show that, by simple fusion with access of air, manganese effects the separation of 7-10ths of the sulphur in the pig iron. Repeated melting, without further addition of manganese, does not produce any considerable effect, and it appears that the proportion of manganese should be large, for by remelting the same metal with a fresh quantity of manganese the sulphur may be almost entirely separated.

	Silicium.	Manganese.
Siliciетted iron	0·99	
No. 1 Silicietted iron melted alone	0·88	
No. 2 Silicietted iron melted with 6 per cent. manganese	1·30	4·77
No. 1 Melted again without addition	0·80	
No. 2 Melted again without addition	1·66	2·98
A. Silicietted iron melted with 10 per cent. iron oxide	0·61	
B. Silicietted iron melted with 10 per cent. iron oxide and 6 per cent. manganese	0·37	2·52
A. Melted again with 10 per cent. iron oxide	0·52	
B. Melted again with 10 per cent. iron oxide	0·18	1·10

The manganese used in these experiments contained silicium, and in this way, as well as by reducing the silica of the crucible, added to the amount of silicium in the iron. But this is not the case when the iron is decarbonized by the addition of iron oxide.

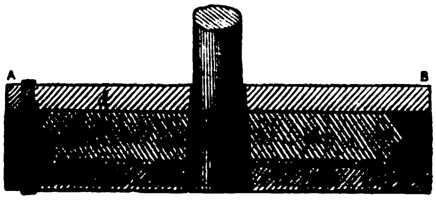
It may be inferred from these results therefore that manganese determines the separation of a large portion of the silicium in pig iron.

These results agree with practical experience. The ores above mentioned, that yield the better kinds of steel often contain sulphur, but never contain phosphorous; and it is a noteworthy fact that, although those ores contain copper pyrites, the pig iron they yield does not contain sulphur.

Although manganese does not determine the conversion of iron into steel, as Karsten has well shown, it is nevertheless certain that—besides rendering steel capable of being welded—it has an influence in improving the quality of steel. M. Caron considers that this influence may be explained by the aid of facts which he has formerly made known. When a sufficient quantity of manganese is added to grey pig iron, the carbon of which is to a great extent in a free state, white pig iron is obtained, in which the carbon is almost entirely in a state of combination. The effect is the same with steel; a very small addition of manganese is sufficient to retain the carbon in a state of combination, and, in consequence, to confer on the metal the characters peculiar to good steel. However, the amount of manganese in steel must not exceed 5-1000ths; more than that renders steel hard and brittle, the surface of fracture becomes crystalline, and the metal is deficient in tenacity.

It is a common practice in refining iron to mix ordinary pig iron with manganiferous pig iron, and the above results show that the beneficial effect of this practice is greater according to the amount of manganese present. It appears therefore to be a point of practical interest to reduce manganiferous ores in such a manner as to obtain the largest possible amount of manganese in the pig iron. The spathic ore of the Siegen district contains from 15 to 20 parts manganese for 100 of iron; but the pig iron made there does not contain more than 6 or 7 per cent. of manganese. M. Caron considers that if this amount could be increased to 10 per cent. the commercial value of the pig iron would be increased.

RIPLEY'S IMPROVED PISTONS.



Mr. A. Ripley, of Lambeth, has just patented an improvement in pistons, which consists in causing the rings composing the packing of the piston to expand so as to exactly fit the cylinder by means of the pressure of the steam, air, or liquid. To effect this a double cone is formed on the periphery of the block or portion into which the piston rod is fitted, the exterior packing ring is placed over this, leaving a small space between the two; within this space is another ring, the interior having the same angle, and accurately fitting one of the cones before mentioned, the outside pressing against the exterior packing ring; a corresponding ring is fitted to the other cone, which also presses against the outside packing ring. Through each cover of the piston are several studs or projections, which touch the edges of the inside rings, so that when the steam is admitted on either side of the piston it will press the studs down, thus acting upon and enlarging the inner rings by forcing them further over the cone, and consequently the exterior packing ring. By calculating the surface of the studs or projections any degree of pressure can be obtained.

The accompanying engraving shows a sectional elevation of a piston constructed as above described.

a is the solid plug or body of the piston, upon the periphery of which the double cone is formed for expanding the ring wedges; *b*, *b*, the cone rings or inner expanding ring wedges; *c*, the outer metal packing ring; *d*, *d*, the covering plates or junk rings in which the miniature pistons *e*, *e*, are fitted; *f*, opening left between the coned ring to allow for this being pressed inwards and expanding over the solid cone when impelled by the force at the steam or fluid acting upon the miniature pistons, thus causing the outer packing ring also to expand and take the exact form of a transverse section of the cylinder at all parts of the stroke, thereby maintaining the steam or liquid-tight condition, notwithstanding any irregularities in the cylinder arising from imperfect boring, previous unequal wearing, or other causes. When necessary, the miniature piston-heads may be fitted with flexible diaphragms for increasing their power, and increasing their steam or vapour-tight action.

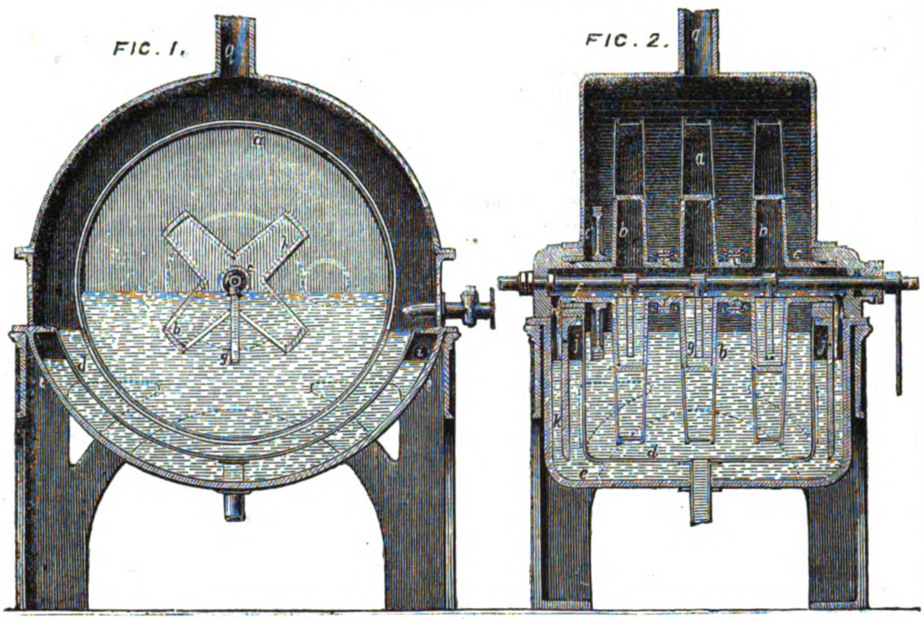
GOLD QUARTZ.

A new method of depriving gold ores of sulphur has been introduced at the mines of Pike's Peak: It consists, says the *Scientific American*, in reducing the ores to fine dust, then forcing the dust by a draft through a flame of pine wood. The furnace used is a square brick structure, with a grate about 3 ft. wide by 4 ft. in length, and 3 ft. high, in which a fire of common pine wood is built. The flame from this fire-place escapes into a chimney built in the shape of a muffle, and, instead of rising upward, runs down toward the lower floors at an angle of forty-five degrees. The tube containing the ground quartz enters this muffle-shaped chimney at its upper end, just where the blaze from the furnace enters, and the strong current carries the flame its whole length. There are several round holes, an inch or two in diameter, at intervals of 3 ft. or 4 ft. along both sides of the chimney. Through these, when the apparatus is in operation, a further supply of air than that furnished by the blower is sucked in and assists in decomposing the sulphur contained in the ore. In passing down the flue or chimney the pulverized ore is blown through a jet of flame, as dust, for a distance of about 20 ft. —the length of the flue—and each particle being separate, is surrounded by air and a strong flame, and it becomes red hot, giving off its sulphur, arsenic, and other volatile constituents. After passing down the flue, it falls into a receptacle of brickwork, whence it is raked out upon an earthen floor to cool. The ore now presents about the same appearance as that burned in a reverberatory furnace—a brick red. The amalgamation machinery is simply an arrastra about 8 ft. in diameter, with a stone bottom and dragstones. This is a very novel process; and three times more gold, it is stated, are obtained by it than by any of the old processes.

Sulphur, arsenic, and iron in quartz prevent, in a great measure, the mercury from amalgamating with the gold.

The *Phare de la Manche* says:—"It appears certain that the Emperor will visit Cherbourg about June 20, for the purpose of inspecting the iron-clad fleet which will then be collected there. The frigates "Couronne," "Normandie," and "Solferino" are at present in dock undergoing repairs, and their officers and crews are to be changed or modified. We learn that the "Gloire" and "Invincible" are under orders to leave Toulon for Cherbourg. The number of iron-clad vessels will be six, as the "Magenta" is to come from Brest, and they will form a squadron, of which it is said that Vice-Admiral Rigault de Genouilly will have the command. It is expected that these six vessels will perform evolutions in the presence of His Majesty."

PEEK'S EVAPORATING APPARATUS.

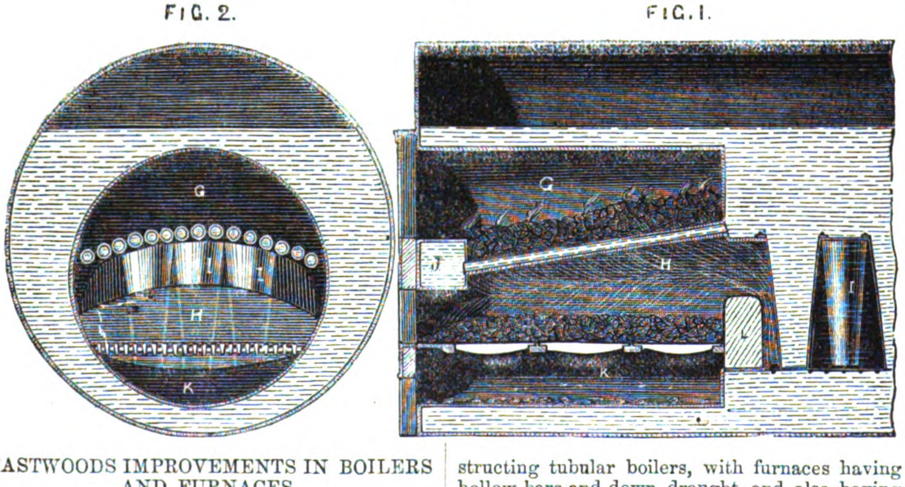


PEEK'S EVAPORATING APPARATUS.

THE above engravings show in sectional views an apparatus for evaporating saccharine and saline solutions, recently patented by Mr. A. Peek, of Manchester. The invention consists in applying the heat necessary for evaporating the solution in such a manner that the temperature of the solution cannot be raised beyond the boiling point of water, but it may be kept to any required degree below that temperature.

a, a, a, are three hollow discs or agitators, made by preference of sheet copper, attached by rivets or otherwise to the arms *b* of the hollow axle *c*. The agitator revolves slowly in the pan *d*, which is placed within the outer pan *e*. The steam pipe *f* passes through the hollow axle *c*, and it is supplied at one end with a stuffing-box, and at the other end with nuts, and a shoulder to prevent the leakage of steam or water through the outer casing of the apparatus. To the pipe *f* are connected the three branch pipes *g*, which are open at their ends to convey the steam from the pipe *f* to the hollow discs *a*. This steam, as it condenses into water, overflows into the passages *h* at each end of the hollow axle *c*, which convey the water into the space between the pan *d* and outer pan *e*; the overflow is carried off through the orifice *i* and through a syphon pipe or trap; the small orifices *j, j*, in the partitions *k, k*, are to allow the water to overflow freely into the space between the pans *d* and *e*. The saccharine or saline solution to be evaporated having been run into the pan *d* through the supply pipe, a slow rotary motion is given to the agitators by means of a shaft, driven by a steam-engine. The exhaust steam from the engine is conveyed to the pipes *f* and *g*, placed, as before described, within the agitators; this exhaust steam supplies the heat required for the evaporation. The orifices of the branch pipes *g* can thus be brought nearer to or above the surface of the water in the agitator for the purpose of heating more rapidly at the commencement of an operation. The vapour rising from the saccharine or saline solution in the pans *d* is carried off by the pipes *g*, which are in communication with a fan. When the requisite degree of evaporation has been obtained, the saccharine or saline solution is run off out of the pans *d* by the pipe beneath. Two or more of these apparatuses may be worked in combination with each other, and may be placed on different levels to facilitate the running of the solution from one pan to the other.

EASTWOOD'S BOILERS AND FURNACES.



EASTWOODS IMPROVEMENTS IN BOILERS AND FURNACES.

A PATENT has been obtained by Mr. H. Eastwood, of Elland, Yorkshire, for improvements in boilers and furnaces. The improvements consist in combining and arranging, or constructing tubular boilers, with furnaces having hollow bars and down draught, and also having a furnace of ordinary fire-bars underneath, whereby a great amount of heating surface is obtained, a rapid circulation of the water therein produced, the fuel economised, and the smoke consumed. The boiler shown is of the cylindrical form, with one fire-box, but having two furnaces or fire-places G and H. The fire-box is joined to an oval fire-flue, in which are a series of vertical tubes or water passages I opening at each end with the interior of the boiler. The grate bars of the furnace G are made of wrought-iron tubing open at one end to the boiler above the flue, and at the other to a water space J, which opens at each end to the boiler, and also forms the dead plate. The grate bars of the furnace H are of the ordinary kind, with an ashes place K underneath; and there is a bridge of brick or fire-clay L to the back as usual. Both furnaces are provided with doors, and those to the upper are perforated to admit air. The upper furnace is supplied with coal, and the flame and smoke, or gases, pass down through the grate bars to the flue. The under furnace is fed with coke and the incandescent fuel or cinder falling from the upper furnace, the flame and intense heat from which, arising and passing towards the flue comes in contact with, and ignites the unconsumed gases and carbonaceous matter passing from the upper furnace. The intense heat of the fires acting on the hollow grate bars generates steam rapidly, which is constantly passing into the steam chamber of the boiler, and water is supplied thereto from the water-space, so that a continous current or circulation is mantained through these tubes; also the great heat in the flue acting on the vertical tubes produces, in like manner, a continual passing of the water from the bottom of the boiler to the upper part, and thereby obtaining a more uniform temperature of the water, consequently more equal expansion and contraction of the parts, and therefore less wear and tear in boilers. It will also be observed that this boiler possesses a great amount of heating surface, whereby steam is generated very rapidly and with great economy of fuel.

UNSWORTH'S IMPROVEMENTS IN STEAM ENGINES.

THIS invention relates to certain combinations of the valves, cylinders, and ports of steam-engines, with a view to avoiding compression or back pressure in the main cylinder. For this purpose, according to one arrangement, the pipes or passages employed to convey the steam to two small cylinders alternately are placed close to each end of the main cylinder, and additional ports, which are to prevent back pressure or compression, are placed within about 2½ in. of each end of this cylinder, so that when the piston reaches the end of the cylinder it covers the port which has been opened to prevent back pressure; but so soon as steam is admitted into the large cylinder it moves the piston valve in the small cylinders, and closes the port upon which the main piston is standing, opening at the same time a port at the opposite end of the main cylinder; this is performed whilst the crank is travelling over the centre. The steam admitted into the small cylinder returns as soon as the exhaust port is opened to the large cylinder; this arrangement prevents any escape of steam. If preferred, the steam may be admitted into the small cylinder or cylinders direct from the boiler.

In another arrangement, a single small cylinder is used in combination with valve boxes attached to each end of the main cylinder, suitable pipes or passages conveying the steam from the large cylinder to each end alternately of the small one. The two valve boxes in connection with the small cylinder are opened in turn as soon as the steam is admitted into the opposite end of the small cylinder, to allow of the escape of the steam under compression in the main cylinder.

Fig. 1 of the annexed engravings represents a longitudinal section of the upper portion of a locomotive or other steam-engine cylinder with these improvements attached; fig. 2 is a corresponding plan of the same; and fig. 3 is a transverse section taken through one of the small cylinders, bed plate, and portion of the main cylinder.

a is the main steam cylinder, and *b* its piston,

UNSWORTH'S STEAM ENGINES.

FIG. 1.

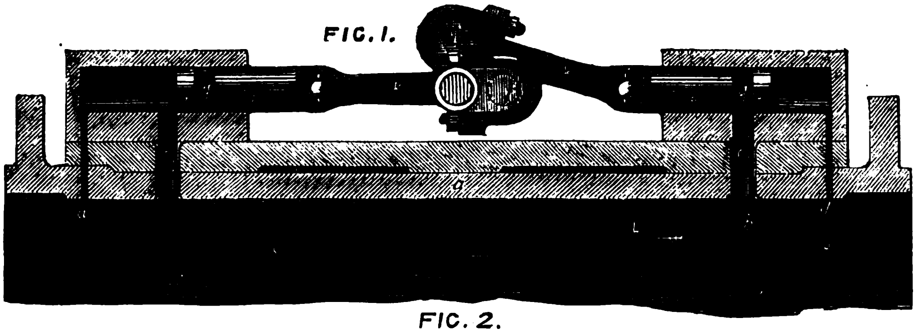


FIG. 2.

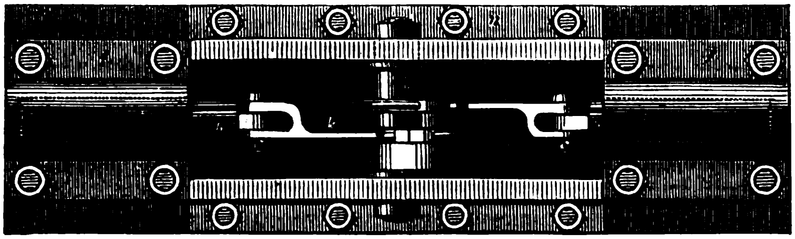

FIG. 3.

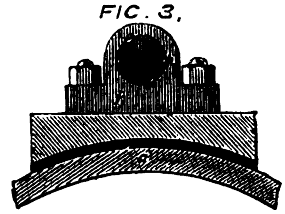
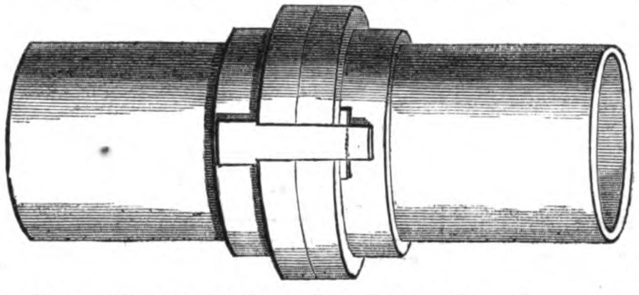


which latter is represented as covering one of the two additional ports *c*, *c*, which are made near each end of the main cylinder for the free escape of the back pressure steam, hereinafter designated as the "compression." A small steam port *d*, *d*, is also made in each end of the main cylinder, leading, like the larger ports *c*, *c*, into the small supplementary cylinders or valve boxes *f*, *f*, within which work steam-tight the piston valves or plugs *e*, *e*. A wide groove or annular recess *g*, *g*, is formed in each piston valve, and into these annular recesses or grooves run a number of longitudinal grooves or slots *h*, *h*, (shown clearly in fig. 3), these longitudinal grooves or channels serving as outlets for the free escape of the "compression;" the two piston valves or plugs *e*, *e*, are connected together, so as to work in concert with each other, by means of the connecting rods *k*, *k*, which are jointed by means of the pins to the outer ends of the plugs; the contiguous ends of the two connecting rods are respectively coupled with the cranks *l*, *l*, set at right angles on a short shaft, which works in brackets bolted down upon the bed plate. To this same bed plate are also bolted the small cylinders *f*, *f*, so that the whole of the apparatus is contained on the bed plate, and may, therefore, be readily fixed to the cylinder of a locomotive or other steam-engine. The piston *b* is supposed to have just completed one stroke, and the port E of the cylinder (in connection with the exhaust) is full of steam, which is confined therein, and exerts a back pressure upon the piston on its return stroke after the exhaust port of the slide valve has been closed. So soon, however, as the steam enters the cylinder *a* on the steam side S of the piston by the usual port and side valve, a portion of the steam passes by the small port *d* into the small cylinder *f*, and by the time the main piston *b* is in motion, the plug or valve *e* in this cylinder has been forced by the steam pressure beyond the port *c*, so as to close all outlet for the acting steam, which would otherwise escape through the part *c* so soon as it was uncovered by the main piston *b*. This forward movement of the plug *e* is transmitted through the cranks and connecting rods to the opposite plug in the other cylinder. The effect of this movement of the plug is to bring the recessed portion over the port, whereupon the "compression" or back pressure steam escapes freely along the grooves or channels in the plug during the full stroke of the piston, and after the ordinary exhaust port has been closed; hence, the resistance or back pressure hitherto exerted against the piston whilst it is completing its stroke is entirely obviated. These valves or plugs are operated in like manner at each stroke of the main piston *b*, the in-coming steam at one end of the main cylinder opening the valve or plug for the escape of the "compression" at the opposite end.

TAYLOR'S JOINTS OR CONNECTIONS FOR PIPES AND TUBES.

The accompanying engraving illustrates an invention patented by Mr. W. Taylor, of Newport Pagnell. The invention consists in forming a flange or collar on the ends of pipes and tubes, in making undercut grooves in the collars, and on the employment of dove-tailed cottars, formed with a head at one end and a slot at the other, for the reception of a key, which cottars slide into the grooves, and are tightened-up by the keys being driven into these slots.



THE LONDON ASSOCIATION OF FOREMEN ENGINEERS.—VAILE'S CHAIN PROPELLER.

At the monthly meeting of the above Society, held on Saturday, the 6th inst.—Mr. Joseph Newton in the chair—the discussion on the principle and details of Mr. Vaile's new system of marine propulsion was renewed. Mr. Walker, who re-opened the question, commenced by saying that, when on the occasion of their May meeting Mr. Newton had so fully explained the action of the new propeller, he (Mr. Walker) was under the impression that Mr. Vaile had simply resuscitated an old scheme of the well-known Symington. It was only fair now to acknowledge that this was not the case. He had compared the two plans of propulsion, and found that they widely differed, the points of difference being all in favour of the more recent one. The floats were attached to the chains in a simpler manner than in Symington's, whilst the feathering properties of the floats and the total submergence of Mr. Vaile's apparatus were entirely novel features. Still, however, he was of opinion, in spite of these palpable advantages, that difficulties of a practical nature would be found to militate against the success of the scheme before them. The number of working parts in the chain-wheels would lead to their derangement, and this was one source of inferiority. The screw was simple, and, if less effective in theory, would be found more durable, and less liable to accident, in practice. He must admit that some strong claims to superiority, as regarded the avoidance of the evils of slip, for example, might be, and indeed had been, advanced on behalf of the Vaile propellers, and in their general principle he himself agreed. It might be possible that his own objections were more imaginary than real, and that an experiment might have the effect of cancelling them. It was difficult for those whose whole experience had been confined to screw or paddle-wheel to divest themselves entirely of prejudice, or to grasp suddenly the ideas of an inventor who left the beaten track and suggested something very different to the prevailing systems of marine engineers.

Mr. Oubridge, apart from some minor objections, which referred solely to mechanical details, believed that Mr. Vaile's efforts were in the right direction, and thought that that gentleman might legitimately hope for a considerable amount of success. The main principle of the submerged feathering-floated propeller was, he believed, correct and in accordance with natural laws. As for less important points in connection with it, a few experiments might set them at rest. This was precisely one of those plans in relation to which the practical test alone must be the final arbiter. The screw and the paddle-wheel had gone through many stages of mutation, and they both had their disadvantages even now. Mr. Oubridge trusted that ere long the propeller of Mr. Vaile would be put into practical competition, and that on a sufficiently large scale with its powerful competitors.

Mr. Ives saw an insurmountable obstacle, as he thought, to the extensive introduction of Mr. Vaile's propellers. In order to obtain anything like speed in a ship fitted with them, the chains would have to travel at the rate of 1,000 ft. per minute, and if this speed were to be obtained by the media of toothed gearing, the wear and tear of the one and the shock to the other would soon prove fatal to both. As to the feathering properties of the floats, he believed that some of the largest steam navigation companies were abandoning feathering floated paddle-wheels, and this was an argument against feathering floats generally.

Mr. Ross considered that the last speaker had jumped at conclusions, rather than advanced towards them by sound reasoning. He saw no objection to the rate of speed at which the chains and floats would have to travel, provided the links and joints were properly fitted; and as to the "shock" to the gearing spoken of, he could not see how it was to arise when the floats were constantly submerged, and the resistance to be overcome was always the same. He believed, moreover, that it was only in exceptional cases that Mr. Vaile proposed to use gearing at all. As a general rule, he understood direct-action engines on the horizontal principle were intended to be employed, and these would be in every way preferable to gearing. As to the abandonment of feathering paddle-wheels, he was in a position to assert that the most recently fitted-up steamship of the West India Mail Company was supplied with them. Looking at the whole plan of Mr. Vaile dispassionately, he (Mr. Ross) was disposed to think most favourably of it.

Mr. Meredith Jones had seen much of the links used in the chains of dredging barges, and his experience led him to disapprove of the introduction of chains for the purposes of marine propulsion. They would, he thought, be found noisy in action and liable to accident. The joints would get "play," and the pins would have a tendency to work loose. The principle of applying the propelling power as low down as possible in the vessel was in itself good, but it was difficult to see how it was to be economically effected.

Mr. Stabler, though approving of the ideas of marine propulsion advanced in Mr. Newton's Paper of the previous month, saw, he confessed, some impediments to their practical establishment. Murray's chain pumps were constructed on a plan not dissimilar to that of the chain propellers, and they could not be worked very rapidly without inconvenience. For Canal, and River navigation, however, he believed the Vaile propeller would be found admirably adapted. He had nothing to say against the principle of the invention. Theoretically, indeed, he must admit that the advocates of the endless chain propeller were right; perhaps it might prove that they were so practically. Time and actual experimentation alone must determine that point.

Mr. Stanley imagined that there would be some trouble in keeping the pitch of the chains equal. There would be a tendency to elongation, which would manifest itself at the outset, and probably increase in a quick ratio.

Mr. Vaile having been called upon by the Chairman to do so, undertook to reply to the various objectors. He explained the mode in which repairs to the apparatus might be effected, supposing them to become necessary, and whether it was applied in a totally or partially submerged position. If the chains were fitted at the joints, as he intended they should be, with steel pins working in hard wood bushes, he thought that the wear and tear would be imperceptible, even after many months' working. The speed at which the chains would be made to travel would vary from 600 to 1,000 ft. per minute, and he saw nothing impracticable about that. As to any shock arising from the action of the float-arms against the guides, such an idea was visionary. The arms, indeed, might be said never to leave the guides at all, as a reference to the diagrams would show. It was his favourite idea to employ direct-action engines with small cylinders and rapid stroke; but if gearing were to be employed in connection with engines of large cylinders and long slow stroke, he imagined that all purposes would be served equally well. Mr. Vaile replied *seriatim* to the other exceptions taken to his plans, and concluded his remarks amid considerable applause.

The Chairman said that before closing the interesting and instructive proceedings of the evening, he should be glad to offer a few remarks. These went to demonstrate his entire approval of the submerged feathering endless-chain propeller, and his belief that some day, and that not a far distant one, it would effect marvellous changes and improvements in Steam Navigation. He had given great attention to the principles and details of the apparatus; and the more he had reflected upon it, the more was he convinced of its practicability and value.

Mr. Newton having announced that two Papers would be read at the July meeting—one by Mr. Muir, of Woolwich, on "Forgings;" and the other by Mr. Stanley, on "A Substitute for the Slide Link Motion"—the discussion closed. Before the meeting separated, a resolution was passed to open a subscription for the assistance of Mr. Robert Armstrong, C.E., whose painful case Mr. Newton introduced to his brother members in a feeling manner.

APPLICATION OF THE PRINCIPLE OF THE DIVING BELL.

A correspondent of the *Colliery Guardian* says that an interesting and successful experiment was last week made at the Dearnley Colliery, near Rochdale, under the following circumstances:—About a month ago, owing to the breaking of the bucket-dagger, the cylinder cover and the engine beams were broken, and during the time required to repair the engine, the water had risen to a considerable height in the shaft. When repaired, the engine worked well till Sunday, the 17th, when it was observed that there was not quite so much water delivered by the pump. This deficiency was more observable on Monday, and on Tuesday it was seen that the pump delivered no water at the down-stroke. It was supposed the bottom valve or "clack" did not close, and other suppositions were made, but they were mere guesses, seeing that some twenty yards of water were in the pit shaft. The engineer remarked that if a diving-bell could be sent down it could be discovered what was the cause of the pump not lifting. The proprietors of the colliery immediately acted on the idea, and believing that a diver might be found who would go down, and possibly not only discover but remedy the defect in the pump, went immediately to Liverpool and called on Mr. Rodrigues, an employer of divers. After a little explanation, Ellis Javons, the diver who was so successful in the "Royal Charter" wreck, agreed to go over to Dearnley and attempt the repair. He went over with another diver, Thomas Allen, but after inspecting the pit, they telegraphed for John Bulmer to assist them. A platform was constructed about sixty yards down the shaft for the air-pump to be worked upon, near to the water. On Thursday morning Javons, being equipped in diver's dress and helmet, was lowered into the water, the pumping engine working very slowly. He had previously very carefully studied the plan of the pump, and had fully explained to him the *possible* causes of the defect. Besides the pipe which conveyed air to the diver, he had a line tied round his body for safety and for signals. After he had been in the water about twenty minutes, a signal was given for the engine to work quick. The diver ascended in half-an-hour, and brought up with him four or five broken screw bolts which had fastened the flange of the pump-tree above the bucket-door, and he said that when the engine worked quickly the water at the down-stroke came out at the joint with such violence that he was hurled to the side of the pit, and at the up-stroke his whole body was drawn with great force against the opening; and it was observed at the top of the pit that the pump worked well at that time, and it was believed for a moment that he had succeeded in mending the pump. In the afternoon, he again went down, taking with him new bolts and a powerful key. He was this time under water an hour and three-quarters, and when he came up, said that he had put all the bolts in, and was screwing the last bolt when he broke it, and cracked the flange, and this necessitated his again going down on the following morning, which he did, and finished repairing the joint and made a careful examination of the rope, the bucket-door, and the joints of the pump-trees, and all he declared to be in good working order. The engine was set to work, and the pump has worked very well. The diver, the proprietors, and the workmen, were all well-pleased at the success of the attempt, believing, too, that in similar doubtful cases the services of the diver may be most advantageously resorted to, and that at a very considerable saving of money and time.

Meetings for the Week.

Mon.—*British Architects.*—At 8 p.m.

Wed.—*Geological Soc.*—I. "Relations of the Sandstones of Cromarty with Reptilian Footprints," by Rev. G. Gordon and Rev. J. M. Joass. Communicated by Sir R. I. Murchison. II. "Tertiary Shells from Jamaica," by J. C. Moore, Esq. Note on the Corals, by P. M. Duncan, Esq. III. "New Fossil Thecidium from the Miocene Beds of Malta," by J. D. Macdonald, Esq. IV. "Sandstones and Shales of the Oolites of Scarborough," by J. Leckenby, Esq. V. "A Monograph of the Ammonites of the Cambridge Greensand," by H. Seeley, Esq. VI. "Geology and Mineralogy of a part of Borneo," by M. C. de Groot. Communicated by Sir R. I. Murchison, at 8 p.m.

Thurs.—*Antiquaries.*—At 8.30 p.m.
Linnæan Soc.—At 8 p.m.
Royal Soc.—At 8.30 p.m.
Chemical Soc.—At 8 p.m.

Fri.—*Architectural. Assoc.*—Class of Design—Cemetery Monument.

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the Mechanics' Magazine at the rate of 6d. per line, or 5½d per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

All communications should be addressed to the Editor, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

A Sufferer.—Your observations are pertinent and sensible; and such a committee as you speak of might prove useful provided it consisted of honest men. The suggestion contained in the last part of your letter proposes nothing more than an act of justice.

T. W.—We regret that it is quite out of our province to aid you.

H. K. (Edinburgh).—We think that, having for the present closed this discussion, it would be unfair to other correspondents to reopen it just yet. Perhaps, at a future day, when fresh facts have accumulated, we may do so, when we shall be happy to hear from our able correspondent.

Received.—J. N.—W. A.—J. W.—F. A. P.—H. K.—J. H.—W. W.—T. T. H.—D. M.—W. B.—R. S.

Correspondence.

◆

FOULING OF IRON SHIPS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—The fouling of the immersed portions of iron ships, both of the Royal Navy and of the mercantile marine of this country, is a subject of such vital national importance, that no really inexpensive means holding out the slightest prospect of success should be left untried.

I beg to send you four proposed mechanical means of preventing the fouling of the immersed portions of iron ships which I have submitted to the Admiralty, but which their lordships decline to bring to the test of experiment. I have now added a fifth mode, and hope that as these proposed plans are generally very simple and inexpensive, that some of the mercantile marine may give some of them a fair trial.

1. Let small dovetail grooves be placed upon the side of the ship from the water-line, or some distance above it, and reaching down to the keel, 2 ft. or 3 ft. apart, and not projecting from the skin of the ship more than 3-16ths of an inch, thus—

Into the upper end of this groove would be inserted a thin plate of steel, which would be pushed down in the groove as far as the keel, and adhering so closely to the skin of the ship as to detach every substance, whether vegetable or animal, which would be attaching itself in an incipient state to the sides or bottom of the ship. This steel plate would then be drawn up and placed into another groove, until the whole of the immersed portion had been passed over by the steel plate or scraper. This process could be carried on while the ship is under weigh, and could be repeated as often as necessary to prevent any accumulation of animal or vegetable matter on the immersed portion of the ship.

It will, no doubt, be objected, that these projecting fillets necessary to keep the scraper close to the side of the ship will themselves form an impediment to the sailing of the ship. This is readily granted to the extent of the thickness of these fillets, and, therefore, experiment alone can prove the utility of this mode of the prevention of an existing evil.

But supposing the whole of the immersed portion of the ship to be covered with moveable steel plates, which would be occasionally drawn out and polished, might not this arrangement so diminish the skin resistance of the ship through the water as to add two or three knots an hour to her speed?

2. Construct a crib or cage large enough to hold a man, air and water-tight, with framework to prevent it from collapsing by the pressure of the water, and to keep the waterproof covering 5 or 6 in. from the side of the ship. In the side of the cage opposite to the side of the ship (and probably also in some other portions of it), a bull's-eye would be placed for light, and sleeves would be attached for the arms of the operator, the palms of the hands being covered with brush. Thus equipped, the cage with the operator securely seated inside, and supplied with air from the deck, would be lowered down, and would commence scrubbing the ship's side opposite to him in vertical strips, as far as he can reach on each side. A rope would also be passed under the keel and taken up at the other side of the ship (and probably fore and aft guide ropes), in order to keep the cage close to the bottom of the ship when passed below the bilge.

By passing this scrubbing process two or three times a week over the immersed portion of the ship, it is presumed that no accumulation can take place. Whether this process can take place when the ship is under weigh or not, experiment alone can prove; but a man-of-war going to sea for a three years' cruise will, doubtless, be able to find some quiet lull to give the vessel's sides a scrubbing as well as the decks. The construction of this crib could be so modified that only the upper part of the covering would be constructed as a frame in order to get rid of the weight and inconvenience of the helmet. An apparatus of this kind would be extremely useful on board of all ships in order to examine any external damage the ship might sustain under water.

3. Pass ropes under the keel of the ship to the deck on each side; to these ropes attach swabs, or rather flat mats, which may, if necessary, be armed with a brush covering. These mats would be so

attached to the ropes as to be kept flat to the side of the ship, and so arranged, that when the mat on one side of the ship would be descending, the other would be ascending. These mats would be drawn up and down several times over the same space, and then passed to a fresh portion of the ship's side. Should brushes be necessary, they should not be so hard as to rub off the paint from the side of the ship.

4. Pass a rope under the keel of the ship and tighten the ends of it to each bulwark, that the rope may be kept close to the side of the ship; to this rope or gasket let a number of points or tails be attached, nearly touching each other, 2 or 3 ft. long, and extending along the whole of the immersed portion of the rope. The vessel being under weigh, these points or tails would float from the rope towards the stern of the ship, and keep up a slight friction against the sides as to prevent or destroy any animal or vegetable substance from adhering to the surface over which these points were kept playing.

The rope would be placed in a fresh position every hour or half-hour, as might be found necessary, in order that every immersed portion of the ship could be passed over as often as would be found necessary to keep the ship perfectly clean.

5. A flexible tube or cone, sufficiently buoyant to float horizontally in the water, about 10 or 12 ft. long, and covered with bristles or flexible whalebone, probably about 6 or 8 in. in diameter; one end of this circular brush would be supplied with a swivel, which would enable it to turn round freely, and to the other end would be attached a light brass or copper screw, adapted to revolve rapidly by the current of water passing along the side of the ship. The apparatus being thus prepared, the swivel end is attached to a rope, which is passed under the keel and taken up at the other side of the vessel. When the apparatus is drawn down to the water and the ship under weigh, it would be carried horizontally towards the stern and put in rapid rotary motion by the current acting upon the screw of the tail end, and thus frictional action would be carried on to any extent over the immersed portion of the ship, by gradually lowering the apparatus as far as the keel, and then passing the rope to a fresh portion of the ship's side. This process could be repeated as frequently as would be found necessary for the purpose of preventing any lodgment of animal or vegetable matter.

Soon after the introduction of steam, it was discovered that concretionary substances became attached to the inside of the boilers, and as it thickened deteriorated the heating qualities of the boiler, and the boiler was also much injured by detaching the concretionary coating. Chemistry did its best to find a solvent, and but very partially succeeded; a mechanical means was then tried, that of frequently "blowing off," and when properly attended to is found simple and efficient. The fouling of ships' bottoms is precisely an analagous case. The evil is great—the accumulation of extraneous matters on the immersed portion of the ship deteriorates her sailing qualities, and injures the skin in the operation of cleaning. Chemistry has been at work for a considerable time, and as yet to very little purpose. Why not give mechanical means a fair trial?

I am, &c.,

Alex. Doull, C.E.

Miscellanea.

We have received a sample of oil from Messrs. Field and Co. We can pronounce it an excellent article, and well adapted to the lubrication of machinery, not manifesting any tendency to glaze or crisp, even after long exposure in a thin film to the atmosphere.

At the Seamless Copper Tube Works at Morrissania, Yew York, pure copper is cast into sound tubular ingots by running the metal into moulds, revolving 2000 times in a minute.

Many of the American iron furnaces are blown with a pressure as high as10 lb. on the square inch; the largest running off 280 tons, of 2,000 lb. each, of pigs weekly.

It is claimed by American agriculturists that Minnesota is a great State for the culture of flax, and as linen can be substituted for cotton almost wholly, the dominion of King Cotton might be disturbed by its cultivation.

We hear that the high and middle level sewers of the main drainage of the metropolis will be partly in operation in two or three months' time, when, perhaps, Father Thames will be relieved of half the title he at present possesses to be considered the largest and filthiest drain in the world.

The "Tyne," the launch of which from the yard of J. Wigham Richardson and Co. took place on Saturday, after being towed up to Newcastle, got her machinery put on board, steamed back to the builders' yard, and was moored there, in the short space of fourteen hours from her launch—an instance of despatch which reflects the greatest credit on the engineering staff of Messrs. R. and W. Hawthorn, by whom the machinery was supplied.

A prospectus has been issued by the General Petroleum Company, with a capital of £200,000, in shares of £10, to carry on the business of an oil refinery and paraffin candle factory upon an extended scale.

The following puff appeared in the City article of the *Times* on Tuesday:—"Mr. Nathan Thompson, whose new process of boatbuilding by machinery is now in operation at East Greenwich, has just invented a method, which promises to become of great commercial importance, for securely stoppering all descriptions of bottles. The stopper is stated to be simple in construction, easy of application, perfectly efficient, and so economical that it will probably come into general use, as by its adoption the necessity of wiring and capsuling would be entirely dispensed with." We calculate the Americans show pretty considerable smartness in availing themselves of the Britishers' press for their own purposes.

A letter has been received from Mr. W. M'Gregor, Chairman of the Institution of Mechanical Engineers, respectfully requesting the patronage of the Mayor of Liverpool to the proposed session of that society in Liverpool in August next, and for his influence in obtaining the gratuitous use of the small Concert-room in St. George's-hall, for the purposes of the society, on the 4th, 5th, 6th, and 7th of the above month. On the motion of Mr. Livingston, seconded by Alderman Bennett, it was resolved that leave be granted for the use of the room.

At a recent meeting of the Liverpool Chemists' Association, specimens of lead-pipe and sheet-lead, electro-plated with tin, were exhibited by Mr. Holt, and some discussion ensued respecting the use of lead coated in this manner for water-cisterns and pipes. It appeared to be the opinion of the meeting that the coating of tin, instead of preserving the lead, was far more likely to ensure its more rapid corrosion; for if the coating of tin by any means happened to be scratched off, even to the slightest extent, galvanic action would take place, and the lead would be destroyed very quickly. Dr. Nevins and Dr. Edwards stated that their experiments had proved that such would undoubtedly be the case; Dr. Edwards remarking that, in one case which he had examined, a cistern made of lead, in which was an accidental admixture of tin, was eaten out by well-water in six months, the lead being rapidly precipitated in the form of sulphate, &c.

A very important decision was come to at the Telegraphic Congress held last week at the Foreign Office, Paris. The concession of a trans-Atlantic submarine cable to M. Balestrini, sanctioned by all the Powers represented at the conference, was formally ratified. The plan is to connect Europe with the Brazils, and the Brazils with North America, so that a despatch from Paris to New York will have to go round *via* Pernambuco. The scheme is a grand one, and its boldness deserves success, but the difficulties in the way of its practical realisation seem formidable in the extreme.

An invention by Mr. Oliver, chief engineer, for preventing the screw from falling after the upper paul is above deck, has been approved by the Admiralty, and ordered to be fitted to the "Orlando." This invention is likely to prove of advantage on board all screw steamers. The "tell-tale," for informing the officials in the engine-room of the direction of the vessel, also invented by Mr. Oliver, has been fitted in the "Orlando."

MM. Delouche and Fellman, an artist and an engraver, have introduced a new method of engraving, which presents many features of interest. They take a plate of polished zinc, which they cover with a coating of whiting analogous to, but not identical with, that employed by wood-engravers; upon this the design is drawn with a peculiar ink. The plate is then suspended in a bath of sulphate of copper from the negative pole of an ordinary galvanic battery, where the inked portions of the drawing become coated with a deposit of copper. When this is considered sufficiently thick, the plate is removed, and having been washed, is suspended from the positive pole of the same battery in a bath of acidulated water. The acid eats into the plate where it is not covered with copper, or the white part of the drawing. A few hours terminate an operation which supplies a plate from which ordinary engravings may be taken in the usual way.

A miniature breech-loading cannon, upon a new principle, the invention of Mr. L. W. Broadwell, of New Orleans, was tried recently at Woolwich, in the experimental range, and gave satisfactory results. The chief recommendations of the new gun are the simplicity of its breech-loading arrangements and the substantial method on which it appears to be constructed, proved by the severe tests to which it was subjected. The gun, when constructed on larger dimensions, is expected to prove a most serviceable weapon. No training is required to initiate the gunner, the method of loading being simply the removal and replacing of a small block of iron to receive the charge. There is a self-acting expanding ring, which serves to seal the breech hermetically at the moment of discharge, and which does not impede the movement of the vent-piece. The projectile used is an elongated shot, simple and plain in construction.

Petroleum for preserving Wood.—The oil wells near Prome, in Burmah, have been in use from time immemorial. Wood both for shipbuilding and house-building, is invaribly saturated or coated with the product of those wells. The result is entire immunity from decay, and the ravages of the white ants that in that country are so generally destructive. M. Crepin, a Belgian Government engineer, who has tried experiments upon the relative advantages of creosote and sulphate of copper for the preservation of timber in marine constructions from the attacts of worms, &c., says that creosoting is the only process he has found to succeed for this purpose. He states that sulphate of copper affords no protection whatever against the action of salt water and marine insects. The Belgian Government now require that all the wood sleepers used in the State railways should be creosoted; and the Government of Holland have also made the same resolution; and upwards of 300,000 sleepers per annum are now being creosoted by the Dutch Government, and more by the Belgian Government.

Wilkinson's Rotary Printing Press.—*Macniven and Cameron's Paper Trade Review* gives a description of this new printing machine, which, it says, will print at least twice as fast as any now used. It will throw off with ease twenty thousand sheets an hour, printed on both sides, cut and folded, ready for immediate delivery. The process of printing with this machine may be described briefly as follows:—The paper being made of the proper width for the sheet intended to be printed, is wound upon a shaft in one continuous piece, in the same form as an ordinary roll of carpeting, and, at the same time, is damped so as to enable it to take a perfect impression. The type, which is slightly conical in form, is placed upon the surfaces of two cylinders, the circumferences of each of which is exactly equal to the length of the newspaper to be printed. Each type is made in the precise line of the radius of the cylinder on which it is placed, and a small projection on one side of the type, with a corresponding indentation on the other, furnishes a means of locking the type together on the surface of the cylinder, so that it is impossible to displace them by the most rapid rotary motion. The machine being set in motion by any ordinary power, the paper is unwound from its shaft by the action of an endless apron, by which it is carried forward and introduced between the first type cylinder and corresponding press roller, where the impression on one side the paper is made. After this first impression, the paper is still carried forward in a direct line, and immediately passes between the second type cylinder and press roller, by which the impression is made on the reverse side. The sheet being now printed on both sides, is still carried forward into the apparatus by which it is folded, and at the precise point when the folding process is completed, a heavy standing shears, by a single blow, separates it from its original roll, and it drops upon the floor a printed newspaper, ready for immediate distribution.

Important Tests of Wire Rope.—Some tests of wire rope took place on Wednesday last week, at the public chain-testing works, Birkenhead, under the superintendence of Mr. Macdonald. The experiments were made for the purpose of testing the wire rigging lately supplied to Messrs. T. Vernon and Son for the new ship "Robert Lees," belonging to Messrs. Liston, Young, and Co., Liverpool. The wire was the manufacture of Garnock, Bibby, and Co. The pieces submitted for testing were as follows:—One piece of galvanized charcoal, 5 in., stood a strain of 36 tons 15 cwt.; the Admiralty test being 32 tons 5 cwt. One piece of galvanized charcoal, 4¾ in., stood a strain of 33 tons 2 cwt.; the Admiralty test being 28 tons 6 cwt. Other ropes from the same manufacturers were also tested, with the following results:—A piece of 4 in. steel stood a strain of 38 tons; a sample of 2¼ in. BB. (or second quality) stood a strain of 7 tons; a sample of 2¼ in. BB. (or second quality) stood a strain of 8 tons 7 cwt.; being in each instance considerably over the Admiralty test for charcoal rope. It is necessary to state that the cores of the above samples were all made of hemp, and not wire, as is now much used; had they been made with wire cores the tests would have been, by estimation, 5 in. charcoal wire rope, a strain of 49 tons; 4¾ in. ditto ditto, 42 tons 16 cwt.; 4 in. steel ditto, 48 tons 13 cwt.; 2¼ in. BB. ditto, 9 tons 14 cwt.; 2¼ in. ditto ditto, 8 tons.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 3073, 3049, 3067.
Boilers and Furnaces, 3042.
Ships and Boats, including their fittings, 3007, 3025, 3061, 3065.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 3018, 3051, 3063.
Cultivation of the Soil, including agricultural implements and machines, 3014, 3031.
Food and Beverages, including apparatus for preparing food for men and animals, 3026, 3032, 3035, 3062.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 3009, 3013, 3015, 3016, 3022, 3023, 3028, 3034, 3045, 3046, 3052, 3053, 3056, 3060.
Buildings and Building Materials, 3039, 3050.

3003. T. Goodyear. *A machine for plaiting straw and such like material.* (A communication.) Dated November 6, 1862.

This machine consists of a roller having a number of curved projections thereon, which roller, through the medium of a winch handle, receives a partial rotation, whereupon certain rods and levers come into operation and effect the plaiting of the straw. *Patent abandoned.*

3004. W. E. Gedge. *An improved lift and force pump.* (A communication.) Dated November 6, 1862.

The pump forming the subject of this invention presents the following advantages:—One, two, three, ten, twenty, or as many pipes or tubes as desired, may be adapted to it. Each tube is isolated, and works separately. It sucks and forces without a reservoir, without valve, and without piston, and works constantly and with the greatest rapidity when provided with water. The air is sucked in by means of rollers or cylinders which press the tubes, and the vacuum fills with the liquid in which the extremity of the tube plunges. This pump is composed of the cylinder or pump barrel, the interior of which is furnished with several pipes or tubes of caoutchouc, leather, or other suitable material. These tubes follow the cylindrical form of the barrel, but do not go completely round, and they come to the exterior one end in the liquid and the other forming the jet end of the pump. Through the centre of the cylinder passes a shaft, supporting in the interior of the cylinder a couple of plates, which sustain three small rollers or cylinders with their pivot on the thickness of these plates. On giving motion to the shaft by means of a crank, the three rollers placed at equal distances apart execute the same movement, likewise turning on their pivot, and it is in accomplishing this movement that they press against the tubes fitted in the pump barrel, and cause the apparatus to work. Another very simple method of action is as follows:—The suction and force pipes or tubes are placed all around the cylinder, their ends issuing to the exterior at the same place, some entering the liquid and the others conducting the jet. A single roller is retained and is fixed to the shaft by two branches, which may be lengthened or shortened by press screws, so as to press the roller against the tubes as much as desirable. *Patent abandoned.*

3005. B. T. U. Monin. *Improvements in breech-loading firearms.* Dated November 6, 1862.

Here the object is to facilitate the rapid loading and discharging of firearms. The invention consists in using and removing a sliding key, which, when removed, opens an aperture leading from the bore of the gun to the butt end or stock. This butt end contains a recess fit to contain several cartridges, which are brought forward by an endless belt or chain running on two rollers. The shaft of one of these rollers carries a pinion, which is actuated by a tooth wheel loose of the shaft of the cock. When the cock is moved back, a catching spring-hook causes the wheel to move, whilst, when firing, the same wheel remains motionless. The whole motion is given by the finger bearing on the trigger; the cock by its back motion not only causes the chain to move and to bring forward the cartridge, but a lifting cam carried by its shaft removes the key, the latter carries along a connecting-rod, which causes a sliding piece to push forward a cartridge into the breech of the barrel, and a spring brings the key to its place, and the gun is ready to be fired off. *Patent abandoned.*

3006. H. Griffin. *An improved method of securing india-rubber cylinders or rollers and blocks upon spindles and other bodies upon which they are to be mounted.* Dated November 6, 1862.

This invention consists in first coating or clothing the spindle or other body on which india rubber is to be mounted with a composition of india rubber for forming what is known as ebonite or hard rubber, and in then adding on such composition to complete the article to the thickness required ordinary or pure india rubber, or rubber known as cut sheet rubber (that is to say, sheets of rubber cut from a solid block), or rubber prepared for being vulcanised. He then subjects the spindle or other body, with its clothings of prepared or hard rubber composition, and ordinary or other rubber as before mentioned, to heat, in order to "cure" the composition. When the curing has been effected, the ordinary or other rubber will be securely held on the spindle or other body through the cured or hard rubber which itself becomes securely fixed to the spindle or other body. *Patent completed.*

3007. W. N. Hutchinson. *Improvements in apparatus or means for protecting the screw of steamers from becoming entangled with or fouled by ropes or other bodies.* Dated November 6, 1862.

This invention consists in the employment of a flexible screen or net on each side of the quarter or after part of the ship, and both fore and aft of the screw, hanging nearly vertically, composed in the upper part of several folds of strong waterproofed canvas, or other suitable material or materials, and partly sustained in the water by corks, or a spar of light wood. The remainder of the screen may be a net (chain or otherwise) of large meshes, say 18 inches wide (made of metal or other suitable material), which, being thin, offers little resistance to the sea, and therefore is not liable to be injured by a sea striking it, nor to impede the ship's progress. In ships with fine rims, the patentee prefers to form the whole screen of net made with Newall's galvanised wire rope. *Patent completed.*

3008. J. A. Fullarton. *Improvements in machinery or apparatus for painting or coating hoop iron and other strips, bars, rods, or other such articles of metal, wood, or other material.* Dated November 6, 1862.

This invention refers to that description of machinery in which rotary brushes are employed, and consists in an arrangement whereby the articles are successively presented to the painting or coating apparatus, and in such manner that a portion of each of such articles may remain unpainted. The invention cannot be described without reference to the drawings. *Patent completed.*

3009. M. A. F. Mennons. *Improvements in the manufacture of paper.* (A communication.) Dated November 7, 1862.

These improvements consist—1, in the addition to paper pulps of albumen, gluten, serum, or other analogous substances, coagulable by heat. 2, in the application to the surface of the manufactured paper of one of these substances, either alone or in combination with coloured or colourless powders of different descriptions. The object of these processes is to produce a glazed paper or cardboard for general printing and photographic purposes, applicable in certain cases as paper hangings, which, being thus coated with a transparent and insoluble matter, may be readily washed or otherwise cleaned at will. The albuminous matter is incorporated with the pulp by any convenient means, the remaining processes of manufacture being carried out in the usual way. The coating of the manufactured paper may be effected either by immersion in a bath of the albuminous matter, or by simple brushing of the latter over the surface. The paper thus treated is then dried and glazed in the ordinary manner. *Patent abandoned.*

3010. C. O. Heyl. *Improved means and machinery to be used for the purpose of extracting fatty oils from oleaginous seeds, and for purifying the said oils, and for extracting the agents employed from the exhausted residue.* Dated November 7, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3011. W. Clark. *Improvements in the means of utilizing refuse and azoted matters of commerce.* (A communication.) Dated November 7, 1862.

The inventor claims—1, the employment of alkaline sulphurets, and especially those of sodium and potassium, for dissolving the azoted matters, either in the open air or under pressure, and also the separation by means of this agent of wool from cotton or other thread in certain cases. 2, he claims the commercial application of the solubility of the said azoted matters in sulphuric acid, either in the open air or under pressure, and the employment of the said acid while saturated with azoted matters for the production of acid phosphate of lime. 3, he claims the saturation of the said acid phosphate of lime with animalized alkaline sulphurets, and also the combination of these reactions in order to produce manure containing azote in various forms, alkaline phosphates, and hydrated phosphate of lime. 4, he claims the direct application of animalized superphosphate obtained by the action of the acid, saturated with azoted matters on the phosphates, in the manner specified. *Patent completed.*

3012. A. V. Newton. *Improvements in repeating firearms.* (A communication.) Dated November 7, 1862.

This invention relates to a modification of certain of the working parts of repeating firearms. The hammer and the trigger are operated by a combination of the main-spring and the scre-spring, which are united at the ends that are fastened to the stock. The main-spring works on the hammer by means of a swivel, and causes the blow of the hammer. The hammer is thrown back by the scre-spring acting on the trigger, and thence through an arm of a forked lever. The rotating cylinder containing the cartridges is made to revolve by means of a flexible arm of the forked lever. This flexible arm works into ratchet teeth cut on the rear end of the cylinder. In its return motion it is free to slide over the teeth, and when in action it pushes round the cylinder so as to bring the next cartridge before the hammer. A small arm is attached to and projects forward from the hammer, and at every blow of the hammer is forced into one of a series of holes in the rear end of the cylinder for the purpose of holding the cylinder firm during the discharge. Fixed ammunition is used in the firearm, and the blow of the point of the hammer, or of a pin held by a spring, discharges in succession the metallic cartridge, whether of pistol, rifle, or carbine. *Patent abandoned.*

3013. T. Greenwood and J. Schofield. *Improvements in mules for spinning and doubling.* Dated November 7, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3014. J. H. Johnson. *Improvements in decorticating grains and seeds.* (A communication.) Dated November 7, 1862.

This invention relates to a chemical process for decorticating grain and seeds of all kinds, in substitution for the mechanical processes hitherto adopted for this purpose. According to this invention, it is proposed to treat the grain or seeds to be decorticated by subjecting the same to the action of acids or alkalies, or acid or alkaline compounds (assisted or not by heat), for the purpose of destroying the outer skin or pellicle adhering to grain and seeds of all kinds, without injuring the kernel of the grain or seed itself, for which purpose also the chemicals employed should be used in a semi-fluid or viscous state. *Patent abandoned.*

3015. H. Gardner. *Improvements in machinery for treating flax and other fibrous materials preparatory for manufacturing purposes, the said machinery being also applicable for pressing, rolling, grinding, pulverizing, or mixing various other substances.* Dated November 8, 1862.

This invention consists of a fluted roller mounted on a frame or carriage; on the top of this roller the patentee places one or more smaller rollers, either fluted or smooth; these rollers are carried and supported on a bell crank, which works on the same centre as the large roller, and this bell crank is driven by means of a crank shaft, which revolves in suitable bearings, and works in slots in the arms of the bell crank, which gives a reciprocating motion to the bell crank, and therefore to the rollers. These rollers are kept in contact with each other by springs, which are regulated by set screws, whereby any required pressure may be given on the material to be operated upon. On the crank shaft is a pinion which drives a counter wheel and pinion, which turns on a pin attached to the side of the frame which works into another wheel keyed on the shaft of the large roller. The pin which carries the counter-wheel and pinion is moveable in slots in the side of the frame, whereby wheels or pinions of larger or smaller diameter may be used, so as to give greater or less speed to the roller, and thus increase or diminish the rubbing or crimping process on the material passing between the rollers. The material to be operated upon is led between the said rollers by feeding cloths or otherwise, as most convenient. When it is required for other purposes than fibrous materials, he makes use of smoothed, turned, rough, or ribbed rollers. The main principle to be observed is, that the gearing introduced should be to effect a slow motion of the large roller, while that of the oscillating frame is much quicker; thus, while the large roller is slowly travelling and carrying with it the fibre or other substance to be operated upon, the oscillating frame moving with greater velocity will cause the smaller roller to travel backwards and forwards on the material many times before the portion immediately in contact with them is carried away by the larger or lower roller. The different rates of speed of the larger and smaller set of rollers will, therefore, be regulated according to the material operated upon, and the effect to be produced. *Patent completed.*

3016. H. Kilshaw and E. Lord. *Certain improvements in power looms for weaving.* Dated November 8, 1862.

This invention relates to that part of the power loom known as the tappets, secured upon the tappet shaft, and employed for actuating the healds, and consists in the peculiar form of tappets to be employed for causing the back healds to rise together and fall lower than the front ones, and whereby an improvement is effected on the surface of the cloth. The invention cannot be described without reference to the drawings. *Patent completed.*

3017. G. H. Ogston. *Improvements in treating nitrous acid and nitric oxide, in order to convert them into nitric acid.* Dated November 8, 1862.

The object of this invention is to recover certain oxides of nitrogen generated in various processes, often treated as waste products, and allowed to escape into the atmosphere, to the great injury to the health and vegetation of the neighbourhood in which such operations are conducted. For instance, nitric oxide and nitrous acid occur as waste products in the manufacture of oxalic acid, by the action of nitric acid upon sugar. The operation being usually conducted either in open vessels or in imperfectly constructed apparatus, the whole of the nitric oxide generated is thrown into the atmosphere and lost. Now, in order to render the nitric oxide so generated available for the reproduction of nitric acid, the patentee effects the decomposition of the saccharine matter in a close vessel of a construction described. In this improved apparatus he causes the nitric oxide, together with any other oxides of nitrogen by which it may be accompanied, to pass through a series of vessels, which he calls condensers, so arranged as to subject these gases to the simultaneous action of compressed air and water, or the vapour of water. He regulates the pressure and temperature, as may be required from time to time as the operation proceeds. *Patent completed.*

3018. C. W. Spruyt. *Improvements in rails for railways.* Dated November 8, 1862.

This invention consists in forming rails in two parts—the foot, the web, and a shoe in one piece, and the top in another piece. The top is shrunk bolted, or otherwise attached to the shoe, and when worn it can be removed, and another top may be fixed on the same shoe. The invention also consists in inserting between the shoe and the top a layer of lead, hardened rubber, or other material softer than iron. *Patent completed.*

3019. W. Simpson. *Improvements applicable to letter-boxes and other like receptacles.* Dated November 8, 1862.

We cannot here give space to the details of this invention. *Patent completed.*

3020. G. L. Locke and J. Clark. *Improvements in the motive mechanism of pianofortes.* Dated November 8, 1862.

This invention refers to the construction of that part termed the hopper, or its equivalent in grand pianos termed the jack, that is, the part secured to the inner end of the keys which in upright instruments serve to act upon the lever to which the sticker is attached, which sticker acts upon the hammer-butt or end. These improvements are intended to attain more perfect action, to afford more power to the blow of the hammer, and greater facility of regulating. This hopper consists of a base firmly secured to the end of the key, this base having a projecting part (termed the fork), with a recess at its end, in which recess is fitted a straight piece, termed the "fly of the hopper," part of which is below and part above the sides of the said recess or fork, to which sides the fly is centered upon a pin free to move. The part of the fly below has the regulator button acting upon it, and this button is secured on the end of a screw-pin that passes into the base of the hopper. The upper part of the fly has the wire spring adjusted at back thereof, such spring being secured to the back of the upper part of the said fly. *Patent abandoned.*

3021. E. Sonstadt. *Improvements in the manufacture of the metal magnesium.* Dated November 8, 1862.

These improvements in the manufacture of the metal magnesium relate—1, to the manner of preparing magnesia or its carbonate, so that it may be in a suitable state for the obtainment from it of magnesium by the process described. 2, to the preparation of an anhydrous compound containing magnesium, chlorine, and sodium, from which magnesium may readily be obtained either by electrolysis of the fused material, or by its reaction with sodium. 3, to the use of iron vessels in which to effect the reduction of magnesium from the said material by means of sodium. 4, to the preparation of an anhydrous chloride of magnesium, and the use thereof for the separation of sodium from metallic magnesium. *Patent completed.*

3022. G. Kent and E. P. Griffiths. *Improvements in apparatus for reducing cocoa berries and other vegetable and animal substances to powder or pulp, and for mashing potatoes.* Dated November 8, 1862.

For the purposes of this invention, a cylindrical vessel is by preference used, though the form of the upper part of this vessel may be varied. At the lower part of this vessel there is formed a bottom or horizontal partition, composed of angular blades, the cutting edges of which radiate from a circle at the centre to the outer circumference of the vessel. The cutting edge of each of these blades or cutters is so formed and fixed in respect to the back edge of the next angular blade, as to come slightly above the back edge of, the next blade; hence, when the nibs or broken parts of the roasted cocoa berries are, as is hereafter explained, driven round against the cutters, they will be cut, and the fine cuttings or powder thus produced will pass through between the spaces where the cutting edges of the cutters overlap, or rise above the back edges of the neighbouring blades. In the central plate of the horizontal partition or bottom above mentioned, is a bearing for an upright shaft or axis, on which is fixed an instrument consisting of several inclined projections, the lower surface of each of which comes in contact or nearly so with the radial cutting edges of the angular plates above described. Such lower edges of the inclines do not radiate from the centre of the axis or shaft, but are at an angle to the cutting edges of the blades; hence, when the axis of the shaft is caused to rotate, the inclined projections from the shaft will cause the nibs, or the separated parts of the cocoa berries, to be carried round by the inclines, and by them will be pressed against the cutting edges of the fixed angular blades. When the apparatus is to be employed in reducing bread or other vegetable substance, or to mash potatoes, or to reduce animal matter which has been pounded or beaten in a mortar or otherwise, a bottom is introduced into the vessel constructed of woven wire gauze in place of the angular blades. The upper part of the axis turns in a bearing in the centre, carried by a frame consisting of three radial arms, which have hook-formed ends, which respectively pass under legs or projections at the upper edge of the vessel. *Patent completed.*

3023. J. and T. Mellodew and C. W. Kesselmeyr. *Improvements in looms for weaving.* Dated November 8, 1862.

This invention refers to the apparatus for making the shed of looms. To effect this operation the patentees use two elements, the one consisting of a tappet or series of tappets, and the other of a pattern chain or equivalent apparatus; the latter of which determines whether the tappets shall be "risers" or "sinkers." The invention cannot be described without reference to the drawings. *Patent completed.*

3024. G. H. Sanborn. *An improved wringing machine.* Dated November 10, 1862.

This invention consists in the arrangement or combination of the different parts of a wringing machine; in the means of adjusting the rollers of the same; and in the mode of adjusting the machine to the tub or washing vessel. The frame of the machine consists of two posts connected at the top by a cross-piece, and below the rollers by rods or other convenient means. The shaft of the lower roller to which the power is applied rotates in boxes fixed firmly in the posts, while the boxes containing the bearings of the upper roller shaft move up and down in grooves or channels in the posts to adapt the space between the rollers of various descriptions. The machine is rendered self-adjusting by means of two pieces or rolls of india rubber, or other suitable material, resting on the moveable boxes, and kept in place by means of a spring bar. The ends of this bar rest upon the india-rubber rolls or pieces, and the pressure upon it is varied as required by an adjusting screw through the top cross-piece. This screw bears upon the centre of the spring bar, thus permitting either end of the said spring bar, and, consequently, either end of the upper roller, to yield independently to the pressure caused by the fabrics passing through the machine. The lower end of each post is forked, or a slit is cut therein sufficiently wide to receive the side of the tub or washing vessel, and also a binding piece or clamp. These clamps are secured to the sides of the posts by means of guide-pins on which they move freely. The machine having been placed on a tub or washing vessel, the clamps are pressed upon the sides thereof by means of set screws, which set screws pass through the same side of the posts as the guide-pins, and secure the machine firmly without injuring the sides of the said vessel. *Patent abandoned.*

3025. E. Connell. *Improvements in constructing ships or vessels.* Dated November 10, 1862.

This invention relates more particularly to the class of ships or vessels constructed with iron or steel frames and external wood planking, and is designed to admit of such planking being fastened by means of copper, yellow metal, or composition bolts or fastenings, in such a way as not to be liable, or so liable as hitherto, to the corrosive action which has been experienced where copper, yellow metal, or composition bolts or fastenings have been used along with iron frames. It is where the bottom planking of the ship is fastened to the "floors," or floor frames, that liability to corrosion has been principally experienced, on account of the pressure internally at that part of bilge water; but, by the present invention, such liability is avoided, or considerably reduced, by fixing or fastening the copper, yellow metal, or composition bolts or fastenings of the planking into beams or floors of wood, such wooden floors being themselves fixed or fastened to the iron or steel floors by iron or steel bolts or fastenings. If desired, this system of fastening may be extended more or less above the floors, and it may be applied to other constructive details of the same or other classes of ships or vessels. *Patent abandoned.*

3026. J. Whitaker. *Improvements in machinery or apparatus for pulping, stripping, and slicing edible roots for cattle.* Dated November 10, 1862.

Instead of employing two separate machines for pulping, slicing, and stripping, or changing several parts of the same machine, the patentee performs all the operations in one machine, and uses a hinged guide or plate to lead the roots to either side, as may be required. He fixes to the driving shaft at each side of the machine a plain wheel, one mounted with one or more knives for slicing, and the other with the knives or tools for pulping. The stripping knives or tools are fixed upon separate plates, which, when required, are screwed to the slicing wheel, there being slots in the wheel to allow the tools to pass through the interior. The hinged guide or plate is placed in the centre of the hopper, and can be turned on either side, so as to guide the roots to the pulpers on one of the wheels, or to the slicing knives or strippers on the other wheel, by which means the three operations of pulping, slicing, and stripping can be performed at different times in the same machine. The runs of the wheels turn in grooves formed by beads in the sides of the hopper, in order to enable the knives or tools to be quite close to their work, and, thereby, slice, strip, or pulp the last piece; and the sides of the hopper are curved and sloped to allow the matters to be delivered from the machine with perfect ease. *Patent completed.*

3027. J. B. Lavoine. *A kitchen range, called "Cuisiniere Lavoine," adapted for cooking, warming the apartments, and generating gas for the use of private families, hotels, or gentlemen's country seats.* Dated November 10, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3028. S. Berrisford and W. Ainsworth. *Certain improvements in looms for weaving.* Dated November 10, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3029. R. R. Holmes. *Improvements in folding chairs and seats.* Dated November 10, 1862.

For the purposes of this invention, on each side of a seat or chair, or at each end of a longer seat, two bars are applied, which cross each other at a point above the seat. These bars are connected together by a pin joint, which will admit of their being both folded together one on the other, and also of their being opened out one from the other, so as to form legs or supports for the seat; and according as the two legs at each side or end of the seat are at any time at a greater or less distance apart, so will the seat be nearer or more distant from the floor or ground. The two bars above mentioned forming the frame at each side or end of the seat are of different lengths above the pin joint, which constitutes their axis of motion. The shorter bar is formed with an elbow, whilst the longer bar is arranged to carry a back, which it is preferred should turn on a neck or axis, and have a certain degree of play, so that the person sitting in a chair may, when leaning against the back, cause the inclination of the back to assume a position most agreeable to the sitter. The seat is below the point at which the two bars are connected, and the seat is attached by a pin joint or axis to the bar which carries the elbow. At each side or end of the seat there is a rack formed or applied, and connecting the two longer ends or supports. At the opposite sides or ends of the chair there is a bar upon which the rack fits, so as to retain the legs or supports from opening or spreading when once the chair or seat is put into a desired position, and there is an india-rubber spring used tending to fold the two bars together when the rack is lifted up or released from the bar. *Patent completed.*

3030. R. J. Chapman. *Improvements in the manufacture of glass and emery paper or cloth.* Dated November 10, 1862.

Hitherto, the powdered glass and emery dust have been sprinkled or sifted on to the adhesive solution spread on the paper or cloth on one side only, but the inventor proposes by this invention to apply the adhesive solution to both sides or surfaces of the paper or cloth, and to sprinkle thereon the powdered glass, or the corn emery, or flour emery, according to the coarseness or fineness of the article required, so that he produces a double surface, each suitable for rubbing wooden bodies, and imparting smoothness and lustre thereto. *Patent abandoned.*

3031. J. Shanks. *Improvements in mowing machines.* Dated November 10, 1862.

This invention relates more especially to that class of machines used for mowing or cutting short grass and vegetables or plants, commonly known as lawn-mowing machines, and it consists—1, in dispensing with the ordinary cutter bracket, with the screw for raising it up and down, and in the substitution therefor of an eccentric brass or other bush, fitted into the frame of the machine. This eccentric bush is fitted with a slotted flange, and, by merely turning it round, the cutter or actual mower is raised or lowered as may be desired, according to the direction of the turning. 2, in the placing or attaching a flap or pendent end to the grass box of the machine when fitted to a delivery apparatus. This arrangement is so fitted that when the travelling end is at one end of the box, the flap at the other end is down, and this part opens when the travelling end begins to move. *Patent completed.*

3032. W. E. Newton. *Improvements in the treatment of maize or indian corn preparatory to grinding the same into flour.* (A communication.) Dated November 10, 1862.

Here the maize is first steeped in a bath of cold water containing a given weight of carbonate of soda in solution. On removal from this bath, the granular matters are submitted to a second steeping in a bath of cold water containing a given weight of hydrochloric acid. The grain is now dried, crushed, or flattened by suitable apparatus, and submitted to the action of a special bolting apparatus, the seives of which are graduated in fineness. We cannot here quote the whole process in detail. *Patent completed.*

3033. J. Easton and J. C. Amos. *Improved machinery for sawing wood.* Dated November 10, 1862.

In carrying out this invention, in order to secure the log from rising with the drag of the saw on its bed while being cut, the patentees keep it drawn down by means of pressing rollers or bowles, carried by vertical water cylinders, in which stationary pistons are inserted, their rods being pendent from a transverse beam of the saw frame. The upper and lower ends of each cylinder are brought into communication by an outside pipe, which allows of the water which fills the cylinders to pass from one side to the other side of the fixed pistons. The water forms an elastic packing between the piston and the lower ends of the cylinder, and serves to retain the bowles of the cylinders in contact with the timber when once lowered in contact therewith. *Patent completed.*

3034. T. G. Ghislin. *Improvements in the treatment of certain foreign plants, and in the application of the fibres derived therefrom.* Dated November 10, 1862.

This invention relates to the treatment of the following South African plants, their families and species, viz.:—Oxalidæ, Hibiscus and other Malvaceæ, Virgilia, Bryonia, Gnaphalium, Ficoideæ, Salicornia, Euphorbiaceæ, Urticeæ, Ficus, Proteaceæ, Cycadeæ, Phœnix, reclinata Indeæ including Watsonia humilis and others, Gladiolus, Antholyza, Lapyronsia, Barbiana, Witsenia, Tritonia, and Sparaxis Juncaceæ Serratus and Tristra; various Resticeæ Cyperaceæ and Gramineæ Holcus, Saccharatus, Maize, and Stipa. By treating these plants according to the special process described, the patentee is enabled to obtain useful fibres of various characters or qualities, which may with advantage be applied to such purposes as hemp, flax, cocoa fibres, hair, and whalebone have hitherto been employed. *Patent completed.*

3035. G. F. Lyster. *Improvements in apparatus for elevating or otherwise transmitting grain and other granular substances.* Dated November 10, 1862.

This invention has for its object the elevating or otherwise conveying of grain and other similar substances from one locality to another in a more expeditious and convenient manner than has heretofore been effected, and consists in the employment of strong currents or blasts of air for that purpose, which currents of air are conducted through tubes to the locality whence the grain or other substance is to be removed, and are there caused to pass into the open ends of other tubes or channels, which open ends are immersed in the grain or other substance, so that the air, on rushing into such tubes, is caused to drag with it the grain or other substance surrounding the orifices, and to propel it along inside the conducting tubes or channels with the requisite velocity for raising it to a certain height, or for conveying it to a certain distance. *Patent completed.*

3036. G. Davies. *Improvements in the construction of crinoline skirts.* Dated November 11, 1862.

In manufacturing these crinoline skirts, the hoops are furnished at suitable distances with a small tape, having a button-hole, which fixes on a corresponding button sewn on the petticoat. Each of the hoops is thus retained by a certain number of buttons (or hooks and eyes may be substituted), and to remove them it is only necessary to unbutton or unhook them. *Patent abandoned.*

3037. W. Booth, J. Booth, and T. Booth. *Improvements in rotary engines.* Dated November 11, 1862.

This invention consists in constructing rotary engines, in the cylinders of which a piston or pistons connected to a central shaft is or are made to revolve by steam, water, air, or other fluid. The patentees adapt a sliding partition to the cylinder by means of levers or otherwise. The steam or other fluid may be cut off from the cylinder at certain periods, to allow it to work expansively. *Patent completed.*

3038. W. Palliser. *Improvements in the construction of ordnance, and in the projectiles to be used therewith.* Dated November 11, 1862.

This invention consists in forming the barrel of concentric tubes of different metals, or of the same metal differently treated, so that as nearly as possible, owing to their respective ranges of elasticity, when one tube is on the point of yielding, all the tubes may be on the point of yielding. It thus differs essentially from the method hitherto prevalent, of equalizing strains on concentric tubes by placing an initial or permanent strain on the external ones. *Patent completed.*

3039. H. Burridge. *Improvements in the construction of fire-proof buildings, and a ready method of extinguishing fires in the same, and in other buildings, warehouses, and shipping.* Dated November 11, 1862.

This invention consists in employing a service pipe or pipes connected to and communicating with one or more perforated pipes or tubes, arranged in the form of a framework or otherwise, and extending under the ceiling, the whole length and breadth of such ceiling, and across it. The patentee recommends that the perforations in the pipes be formed in their upper and lateral sides. The said service pipe is also connected to and communicates with a hose, attached, as desired, to a supply of water. *Patent completed.*

3040. J. J. Parkes. *Improvements in lever bell-pulls.* Dated November 11, 1862.

This invention relates, principally, to that class of lever bell-pulls used in sitting-rooms, and usually let into recesses in the walls, and consisting of a circular box, more or less ornamental on the exterior, from which a lever handle projects. In ordinary this lever acts on a barrel winding up a chain, which pulls the wire, and so rings the bell. Instead of the chain connection, the patentee applies a crank arm and pin on the axis of the lever handle, or the crank pin may be on the lever handle itself. The crank pin takes upon a lever, to the end of which the bell wire is attached. The wire lever he makes as long as may be necessary, and equal to the full diameter of the box; or it may be beyond that limit if a suitable fulcrum be provided. By making this lever of such length, the arc that it describes is but very slightly curved, and serves to give almost a straight pull on the wire, and sufficiently near a right line for the purposes required. The pull of the bell spring and wire serves to bring the lever bell-pull back to position after pulling the bell as usual. A suitable groove is made in the crank pin to receive the edge of the wire lever, which keeps it in position sideways, for which reason it may be mounted very loosely on its fulcrum. He constructs the several parts of this apparatus so that the box may be fixed to the wall, and all of the parts of the pull applied thereto subsequently with great facility one after the other. *Patent completed.*

3041. E. Marriott and S. Holroyd. *Improvements in the purification of gas, and in obtaining certain useful products therefrom.* Dated November 11, 1862.

In purifying gas, the patentees use a combination of sulphate of iron with ammonia; and in carrying out this part of the invention, they take ammoniacal gas liquor, and add a solution of iron, so as to precipitate all the sulphides, and leave a slight excess of iron. This excess, however, must not be sufficient to neutralize all the ammonia present, but must leave the solution with a decided alkaline reaction. The quantity of iron to be added will vary with the composition of the gas liquor, but the fact of all the sulphides having been precipitated will be readily ascertained by test in the usual manner. The solution thus obtained they use by pumping it continuously through the ordinary gas scrubbers, but as the iron will become decomposed during the process of purification, small quantities must from time to time be added. The necessity for such addition may be ascertained by the character of the gas as it passes off; if it be foul, more iron is then required, just after the same manner as the condition of the ordinary lime purifiers is ascertained. Secondly, the invention consists in treating the gas with sulphide or sulphuret of iron, and this necessarily takes place in carrying out the first part of these improvements. The invention, however, also consists in the use of sulphide or sulphuret of iron derived from other sources for purifying gas, either in the wet or the dry way. *Patent completed.*

3042. W. Harper. *Improvements in the construction of steam boilers and other furnaces.* Dated November 12, 1862.

The object of this invention is to increase the combustion of smoke, and the manner of accomplishing this is as follows:—The bridge of the furnace, instead of being of solid brickwork, as now customary, is made of perforated blocks of fire brick, or other suitable material; and, instead of leaving a passage for the smoke between the top of the bridge and the under side of the boiler or flue, the bridge is built up to the under side of the boiler or flue, thus causing the smoke to pass through the perforations above referred to; and, as the blocks in which the perforations are made are heated by the fire of the furnace, it is evident that the smoke, in passing through the perforations, becomes ignited, and it is thus advantageously disposed of, instead of making it escape to the chimney. In some cases a bridge of the ordinary construction may be used in combination with the perforated bridge. *Patent abandoned.*

3043. W. and J. Galloway. *Improvements in machinery or apparatus for cutting, shaping, punching, and compressing metals.* Dated November 12, 1862.

This invention has reference to a previous patent of the year 1859, No. 526. The patentees claim, firstly, the application of preparatory rams for pushing the metal down into the dies, and, in some cases, for partially performing the operation upon them, which is to be completed by the finishing rams, substantially as described. Secondly, surrounding the dies upon the die tables with water for the purpose of keeping them cool. Thirdly, the employment of a steel bed plate on the top of the die tables, upon which the dies rest, so as to prevent injury to the die tables. Fourthly, fixing down the dies on to the die tables, in the manner described. Fifthly, the mechanism described for actuating the step by step rotary motion of the die tables. Sixthly, the arrangement described for regulating the exact extent of motion of the die tables. Seventhly, the arrangement described for actuating the cutting levers for cutting off the lengths of metal. Eighthly, the combination of any one or more of the various improvements described as constituting the present invention with the machinery or apparatus for cutting, shaping, punching, and compressing metals, as described in the specification, to the hereinbefore mentioned letters patent granted to James Howden, in the year 1859. No. 526. *Patent completed.*

3044. G. Smith. *Certain improvements in obtaining colouring matter.* Dated November 12, 1862.

In obtaining colouring matter according to this invention, the inventor mixes suitable proportions of nitric acid and aniline, that is, any preparation in which the latter exceeds the former. He then heats the mixture, and adds thereto arsenious acid, until it becomes of a rich red or purple colour. And the colouring matter so produced, when dissolved, can be used for dyeing or printing. What he claims as the invention is the treatment with arsenious acid of the mixture produced by heating nitric acid and aniline together. *Patent abandoned.*

3045. W. Dobson. *Improvements in apparatus used in dressing lace or other fabrics.* Dated November 12, 1862.

This invention consists in the employment of a spindle of any required dimensions, and arranged in a convenient manner, having within itself a series of rollers, each roller revolving on the spindle. By the use of a spindle thus constructed, the starch or "dress" may be imparted to the lace in a more regular and equal manner than by the means heretofore employed, besides effecting a saving of time and material. *Patent abandoned.*

3046. C. Socin. *Improvements in looms for weaving ribbons.* Dated November 12, 1862.

This invention consists in a novel construction and arrangement of shuttle frame and shuttles, according to which the guide grooves for the shuttles and the shuttles are curved in a circular line, by means of which considerable economy of space is effected, and other advantages are obtained. *Patent completed.*

3047. T. Bradford. *An improved clothes' wringer and mangler; the acorn wringing and mangling machine, applicable to pressing the liquid from clothes in the process of washing and other pressing purposes.* Dated November 12, 1862.

In carrying out this invention the patentee employs a spring of wood, or other suitable material, consisting of a bar having one or more slots sawn or slotted in it from each end to as near the centre as may be found desirable, similar to a music tuner with one or more tongs. In these slots, when required, he inserts sheet india rubber of suitable thickness, and in the centre or solid part of the bar or spring he makes a hole, through which is passed the plain or unscrewed part of a compressing screw, having the head or knob of an acorn shape, the bottom part of which is loose upon the shank for anti-frictional purposes. The shoulder of the head or knob presses upon the bar or spring, and the worm or thread is received in a nut held in a cross stay fixed to either wood or metal framework, and which, on account of its convenience and utility, is specially adapted to washing, wringing, and mangling machines. By turning the screw with the acorn head or knob inwards, the ends of the spring bar are compressed to any required degree upon T head bolts, forming the communication between the ends of the spring bar and the journals of the upper roller for wringing or liquid pressing purposes, when such rollers are made or covered with india rubber, or other elastic material, and also for various other purposes, such as calendering, when the rollers are made of wood, or other suitable material. The great advantage of the improved spring bar consists in its yielding or reciprocating to the various inequalities of the articles required to be operated upon. *Patent completed.*

3048. F. J. Clowes. *An improvement in obtaining rotary motion.* Dated November 12, 1862.

This invention consists in substituting a cam or cams fixed on a straight shaft in lieu of cranks, as at present in use, and running the ends of such shafts in bearings in the following manner:—In the first place the cam is grooved on its outer periphery, in order to receive a strap or chain which works round a pulley in the lever of the treadle. Secondly, the patentee runs the ends of such shafts in friction boxes; the friction wheel or wheels at either end may be also grooved in order to receive an elastic band, which may be of any flexible substance. This combination is equally applicable to lathes, sewing machines, or, in fact, to any machine in which rotary motion is obtained by treadle action. *Patent completed.*

3049. J. Faulding. *Improvements in locomotive engines.* Dated November 12, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3050. J. H. Thomson. *Improvements in machinery or apparatus for finishing and dressing tiles and similar articles of clay.* Dated November 12, 1862.

Under one modification or system of arrangement, this machine consists of an open rectangular framing formed of wood, or other suitable material. On the middle longitudinal rails of the framing are arranged the pedestal blocks and bearings of a transverse horizontal shaft, which is driven from a steam engine, or other prime mover. A pinion on the end of this shaft gives motion to a wheel which is fast to a second shaft, parallel to the driving shaft, and nearer to the end of the framing. At each end of this shaft, but inside the framing, is fitted a pulley, and the two are connected together by transverse bars, so as to form an open drum. A corresponding arrangement is fitted at the other end of the machine, and round the two is carried an endless band or traversing platform, on which the article to be finished and dressed is laid. The endless band is formed of links of metal of a rectangular figure, connected to each other by transverse pins, or arranged in any other convenient manner. To the links of this chain metal slabs are bolted, on the surface of which the plastic material is laid. A few only of these slabs are used for laying on the plastic material, and these slabs are each fitted with a back bracket piece or stop, which prevents the clay from being carried off the slab by the action of the dressing and finishing apparatus. This consists of a pair of A shaped standards, which are bolted down to the top rail of the framing, and are connected by a transverse tie rod. One of the angular faces of each standard is slotted, so as to admit of fitting thereto an adjustable tool, which is somewhat similar to a plane iron in its action. A mass of the clay or plastic material having been laid on one of the slabs fitted with the back piece, as the endless chain moves forward, the plastic material is cut to a uniform thickness, and at the same time dressed and finished by the action of the dressing tool. Meanwhile the workman places another supply of clay on the next operating slab, and in this way the manufacture of tiles, fire clay, flue covers, furnace blocks, and other generally similar articles proceeds with great rapidity. The dressed and finished articles are carried forward to the other end of the machine from whence they are removed in any convenient manner. At the back of each operating slab the contiguous slab of the chain is omitted, so that the refuse clay removed by the dressing tool falls through the aperature thus provided on to a shoot beneath. By shifting the dressing tool up or down, tiles or slabs of any required thickness may be readily made. *Patent abandoned.*

3051. J. A. Duntze. *Improved apparatus for communicating rotary motion to shafts or axles for various purposes.* (A communication.) Dated November 12, 1862.

This invention relates to various improvements upon an invention for which letters patent have been granted to William Austin Ashe, bearing date the 28th day of March, 1862, No. 863. According to Mr. Ashe's invention, a driver, stud, pin, or tooth, which is connected with the piston of a steam engine, is caused to work in a groove cut in or secured to the shaft to be driven, and which passes through the steam cylinders. It has been found that causing the propeller shaft to pass through the steam cylinder is sometimes inconvenient, inasmuch as the shaft, when it passes through the piston, requires packing, which cannot be got at with facility. The present invention obviates this inconvenience, and (supposing the improvements be employed to drive the propeller shaft of a steam vessel), the steam cylinders are to be placed alongside the propeller shaft, which is, consequently, outside the steam cylinders, and the pistons or piston rods of such cylinders are made to communicate a reciprocating motion to the drivers or stud pins, which are caused to reciprocate in a double helical groove cut in or secured to the shaft, and by this means communicate a rotary motion to the shaft. *Patent completed.*

3052. A. Graemiger. *Improvements in looms.* Dated November 12, 1862.

This arrangement consists in arranging a jacquard apparatus in a loom, in such a manner as to cause the shuttle-box to rise and fall, in place of making it raise and lower the threads of the warp. *Patent completed.*

3053. A. Twaddell. *Improved arrangements for dressing or sizing warps.* Dated November 13, 1862.

This invention consists in so arranging machinery for dressing or sizing warps; that temporarily separated portions of the warps may be independently dressed or sized, and be combined with the rest of the warps before or when passing upon the drying cylinder. *Patent completed.*

3054. G. W. Rendel. *Strengthening and hardening cannon made wholly or partially of carbonized iron or steel, or the barrels or other parts thereof.* Dated November 13, 1862.

In carrying out this invention, the inventor brings the cannon, or the parts of cannon, to a suitable heat in an oven, or any convenient furnace, and he then plunges them into a bath of oil, or other liquid; or, instead of plunging the cannon, or parts of cannon, he pours the liquid over them. To keep down the temperature of the liquid—which is raised in the act of cooling the cannon, or the parts thereof—he employs pipes winding through the liquid, in which pipes a current of cold water circulates, or the liquid may be cooled by any other suitable arrangement; but any arrangement for the cooling is not essential to the process of strengthening, being only a matter of convenience, as having the effect of reducing the volume of liquid necessary for cooling large masses of metal. *Patent abandoned.*

3055. G. W. Rendel. *Strengthening armour plates made of carbonized iron or steel.* Dated November 13, 1862.

In carrying out this invention, the inventor brings the plates to a suitable heat in an oven, or any convenient furnace, and he then plunges them into a bath of oil, or other liquid; or, instead of plunging the plates he pours the liquid over them. To keep down the temperature of the liquid—which is raised in the act of cooling the metal—he employs pipes winding through the liquid, in which pipes a current of cold water circulates, or the liquid may be cooled by any other suitable arrangement; but any arrangement for cooling is not essential to the process of strengthening, being only a matter of convenience, as having the effect of reducing the volume of liquid necessary for cooling masses of metal. *Patent abandoned.*

3056. T. C. and J. Eastwood. *Improvements in machinery or apparatus for combing wool or other fibrous substances.* Dated November 13, 1862.

This invention consists in the employment of a series of combs, each mounted upon a stem or arm, constructed or formed so as to be capable of sliding in a continuous groove or groves of suitably formed framework, and carrying the combs into contact with ordinary feeding heads or nipping rollers, which supply wool or other fibre to be combed. The said combs detach tufts therefrom in succession, the ends of which tufts are cleansed by card surfaces. The combs, when thus supplied with fibre and cleansed at the projecting ends, are caused to travel forward and turn on their stems or arms, so that the combs are in succession placed end to end with each other, thus forming a continuous travelling comb or chain comb, from which the fibre is drawn off in sliver by ordinary drawing-off rollers, and the wool removed by the usual means. The combs thence pass forward in the circuit, and again turn on their stems, assuming their former position before coming into contact again with the feeding heads, from which they receive another supply, and so on continuing to circulate in the groove or grooves of the frame. *Patent abandoned.*

3057. J. Stack. *Improvements in nursery swings and cots.* Dated November 13, 1862.

This invention has for its object improvements in swings, swing chairs, beds, cots, and other similar articles for nursery, house, or other use, and for recreation and other purposes, whereby the same are rendered self-acting, or capable of maintaining the motion imparted to them for a considerable time, without domestic or other superintendence. The improved swings are made in a portable form, and these, as well as the cots and other articles, when required, can be fitted with spring or other power, to give the starting-motion. The motion thus or otherwise imparted, is rendered self-maintaining by the improved and counterbalancing principle of construction described in the specification. *Patent completed.*

3058. M. Defries. *Improvements in the manufacture or construction of lamps.* Dated November 13, 1862.

The patentee claims the combination of an earthenware pedestal or stand with an earthenware reservoir, each being manufactured in separate parts, forming, when the reservoir is fitted to the pedestal, and the burner to the reservoir, an improved lamp for paraffin and other oils, as described. *Patent completed.*

3059. W. E. Gedge. *An improved machine, working by compression and expansion of air.* (A communication.) Dated November 13, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

3060. R. and P. Sykes. *Improvements in rings used in machines for the continuous spinning, doubling, and twisting of wool and other fibrous materials.* Dated November 13, 1862.

This invention relates to the manufacture of the rings used in substitution for the ordinary flyers employed in machines for spinning, doubling, and twisting wool and other fibrous materials; and consists—1, in making such rings of malleable cast iron, and afterwards hardening the same by the agency of heat, the same being used in the same manner and for the same purpose as the glass rings described in the specification of letters patent granted to the present patentees on the 27th day of January, 1860, No. 208. 2, in varying the form of the said rings from that represented and described in the specification of the patent above referred to, so as to dispense with the bead or rounded projection on the inner side, at the upper part thereof, which bead is intended to prevent the ring flyer from leaving the ring during its rotation. *Patent completed.*

3061. E. S. Ritchie. *Mariners' compass.* Dated November 13, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3062. G. Davies. *Improvements in preserving provisions.* (A communication.) Dated November 13, 1862.

This invention consists in causing a current of electric fluid to pass through the cases containing the provisions after they are finally closed up. The electric fluid is made to pass along a fine iron or other metallic wire through the case, which causes the wire to become red hot and consume the oxygen. A further improvement consists in placing inside the case (and in connection with the thin wire) any known chemical agent (such as common sulphur, for instance) which, in its ordinary state, has no particular affinity for oxygen, but which, upon becoming ignited, by means of the electric wire above referred to, evolves any gas (sulphurous acid gas, for instance) which will absorb, destroy, or convert into a harmless gas the oxygen which is contained in the case, and which it is desired to get rid of. *Patent abandoned.*

3063. R. A. Brooman. *An improved means or apparatus for shunting trains.* (A communication.) Dated November 13, 1862.

The object of this invention is to enable a train to be shunted or moved from one line of rails to another without the aid of an attendant. The invention consists in fitting to the front or side of locomotives, tenders, or carriages in front of a train, a projecting rod or rods, which comes or come in contact with a weighted lever or levers at the side of the rail, which, through the medium of rods or chains, draw the points together, and cause the course of the train to be diverted. *Patent completed.*

3064. E. Joseph and J. Danks. *Improvements in brushes, brooms, and mats.* Dated November 13, 1862.

These improvements relate to means of combining hair, cocoa nut, or other fibre into the forms desired for the production of brushes, brooms, and mats. For this purpose, the inventors first weave or otherwise combine the fibres to be used into a sort of fringe. They then apply to the back or combined edge of this fringe a solution of shellac, or other suitable cement, and they then fold or lay the fringe so produced with the back or combined edge thereof in layers together, leaving the front or loose ends thereof free. A convenient method of obtaining the forms desired is to begin at the centre, folding the fringe round and round upon itself to the desired size. They then apply a solution of marine glue or other adhesive matter to hold the parts together, and a back of flexible or other material, according to the purpose to which the brush, broom, or mat so produced is to be applied. *Patent abandoned.*

3065. C. G. Kopisch. *Improved apparatus for propelling, steering, and ventilating vessels.* Dated November 13, 1862.

This apparatus may be described as a furnace contained within, and extending from end to end of, an elongated horizontal steam boiler, below which is situated an air reservoir. The reservoir is supplied with air by a pumping or blowing engine of any ordinary or suitable construction, which air the patentee proposes to draw from the hold of the ship, and bring the various cabins into communication by air pipes, for the purpose of effecting their ventilation. This pumping engine is to be worked by a steam engine, supplied with steam from the steam boiler. The air reservoir is brought into connection with the ash-pit of the furnace by pipes, which supply air under pressure to the fire-place. The furnace is connected at its rear end with a chimney, by two openings of different diameters, both of which are capable of being easily closed. From the furnace also lead off air trunks, the outer ends of which open into and below the surface of the water. These trunks serve to conduct columns of air rearwards, and direct them into the water; and it is by the pressure of these columns of air upon the water that the ship is propelled in any desired direction. *Patent completed.*

3066. E. S. Cathels. *Improvements in the apparatus used in the manufacture of gas.* Dated November 14, 1862.

We cannot here give space to the details of this invention. *Patent completed.*

3067. E. B. Wilson. *Improvements in the method of conveying air, steam, gases, and fluids to oscillating or vibrating cylinders and vessels, and in the apparatus employed therein.* Dated November 14, 1862.

This invention relates to a peculiar mode of forming the connection of a steam, blast, or other pipe with an oscillating or vibrating vessel or cylinder. As an example of the application of this invention, in lieu of the ordinary method of conveying air to the atmospheric converting vessels oscillating on trunnions employed in the manufacture of iron and steel—namely, by passing such supply of air through the trunnions of the same, it is proposed to bring the blast-pipe centrally with, but disconnected from, the trunnions or centres on which the vessel turns, and as near to the same as may be convenient, at the end of which pipe a suitable connecting joint is made, that will allow the pipe to revolve freely, such pipe being in the form of a radial arm, and connected at the other end with the atmospheric vessel. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated March 9, 1863.

648. H. A. Bonneville, 24, Rue du Mont Thabor, Paris, A new aromatic vinegar for removing stains from cloths and other materials. (A communication.)

Dated May 2, 1863.

1108. H. Myers, 55, Rue Meslay, Paris. A new apparatus for indicating appointments or fixed engagements.

Dated May 9, 1863.

1169. E. R. Clark, Drayton Villa, Thistle-grove, West Brompton. An improvement in the construction of portable wine cases or bins for domestic use or export and a pic-nic chest combined.

1169. N. Legendre, 89, Chancery-lane. Improvements in the construction of scissors.

Dated May 12, 1863.

1192. W. Whiteley, Prospect Iron Works, Lockwood, York, iron and brass founder and machinist. Improvements in looms for weaving.

1197. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in machinery for preparing, dressing, and winding cotton, woollen, flax, silk, and other warps. (A communication.)

Dated May 13, 1863.

1200. H. Wilde, Manchester, engineer. Improvements in electro-magnetic telegraphs.

Dated May 15, 1863.

1226. J. Patterson, Beverley, engineer. Improvements in machinery or apparatus for grinding, crushing, cleaning, and hulling or shelling various kinds of farm or vegetable produce, also applicable to the crushing or grinding of minerals and other substances.

Dated May 16, 1863.

1228. R. W., W., and T. Waddington, Thornton-road, Bradford, machine comb makers. Improvements in combs for combing wool by machinery.

1229. B. Browne, 49, King William-street, City, civil engineer. Improvements in the manufacture of elastic material. (A communication.)

1239. J. Whitehead, Calverley, near Leeds. Improvements in motive power machinery, especially adapted for raising and forcing water and other liquids or fluids, parts of said improvements being applicable to steam engines and other machines fitted with pistons.

Dated May 18, 1863.

1241. W. Watson, Clipstone-street, Fitzroy-square, bread and biscuit baker. Improvements in the manufacture of bread and in apparatus used for the same.

1243. A. Heather, Devonshire-house, Southsea, Hants, and J. Redfern, Cumberland-road, Southsea. Improvements in the construction of steam boilers for marine, locomotive, and stationary engines.

1244. B. Hebblewhite, Kingston-upon-Hull, draper. Improvements in machinery or mills for crushing or reducing oil cake, seeds, and other substances. (A communication.)

1245. R. Fenner, envelope manufacturer, and W. H. Hight, engineer, Red Lion-court, City. Improvements in envelope folding machines.

1247. J. Beaumont, Moate, Westmeath, scribbling engineer. Improvements in condensing machines for working yarns of wool and other fibrous substances.

Dated May 19, 1863.

1248. C. Barnard, J. B. C. Barnard, jun., and G. Barnard, Norfolk Iron Works, Norwich, engineers. Improvements in lawn mowing and rolling machines.

1249. S. Rhodes, Farnworth, Bolton, builder. Improvements in machinery for twisting and doubling cotton, hemp, flax, and other like fibrous materials.

1250. J. Edwards, 29, Basinghall-street. Improvements in the permanent way of railways.

1253. R. Bunting, Sheffield, cutler. Improvements in frames, tips, and bolsters used in cutlery, and in securing handles or scales therein or thereto.

1254. H. J. Olding, Belvidere-road, Lambeth, engineer. Improvements in treating flax and other fibrous plants in order to prepare the fibres thereof for spinning, and in apparatus employed therein.

1255. J. Kelly, Brook Lodge, Ireland, civil engineer. Improvements in the preparation or treatment of peat or turf and the manufacture thereof into charcoal and other fuel, drain pipes, building and other tiles, and in apparatus used therein.

1257. L. Chandor, New York, gentleman. An improved mechanical lamp.

1259. L. Chandor, New York. An improvement in lamps.

1260. W. Smith, Mauchline, Ayr, gentleman. Improvements in transferring plain or coloured prints or designs to wood or other surfaces.

Dated May 20, 1863.

1261. H. Wren and J. Hopkinson, London-road Iron Works, Manchester, mechanical engineers. Improvements in the construction of self-lubricating bearings for shafts and axles.

1263. W. J. C. Lang, Kirkcudbright, Scotland, gentleman. Improvements in the manufacture of certain articles to be used for preserving life at sea and other purposes.

1265. R. R. Jackson, Blackburn, cotton spinner and manufacturer, and W. Pemberton, loom overlooker. Improvements in looms for weaving.

1267. J. T. Markall, Fieldgate-street, Whitechapel. Improvements in machinery for working of wood.

Dated May 21, 1863.

1268. J. Cassell, La Belle Sauvage-yard, Ludgate-hill. Improvements in the treatment of mineral oils and hydrocarbons. (A communication.)

1269. G. R. Harding, Wandsworth. Improvements in the means of transmitting power on railways worked by vacuum or the pressure of air, and in the apparatus to be employed for such purpose.

1271. J. Steart, 5, James's-road, Bermondsey, manufacturer. Extracting the fibre from zostera marina and other aquatic vegetable productions.

1275. N. J. Amies, Manchester, small ware manufacturer. Certain improvements in the manufacture of elastic webbing.

1277. W. H. Clapp, North-place, Ball's Pond-road. An improved rail or holder for coats or other articles.

1279. J. Fawcett, Huddersfield, cattle food manufacturer. Improvements in the preparation of food for cattle, horses, and orher animals.

Dated May 22, 1863.

1283. C. Maschwitz, Birmingham, merchant. Improvements in stoppers or bungs for closing or stopping bottles, jars, and other vessels, and the muzzles of rifles, and for other like purposes. (A communication.)

1284. T. A. Blakely, Montpelier-square. Improvements in ordnance.

1285. J. J., J. M., and M. H. Habershon, Rotherham, York, rolling mill proprietors. Improvements in machinery for rolling, polishing, straightening, and tapering round rods or bars of iron, steel, and other metals.

1286. T. A. Blakely, Montpelier-square. A new method of rifling guns, and of forming projectiles to correspond therewith.

1287. G. Stevens, Victoria-terrace, Camberwell. Improvements in coke ovens, and in building and heating ovens or retorts for generating coal gas connected therewith.

1288. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in the manufacture of waterproof fabrics. (A communication.)

1289. W. E. Newton, 66, Chancery-lane, civil engineer. Improved machinery for the manufacture of waterproof fabrics. (A communication.)

1290. J. Higgins, machine maker, and T. S. Whitworth, manager, Salford. Improvements in machinery or apparatus for roving, spinning, and doubling cotton and other fibrous materials.

1291. A. W. Hofmann, Fitzroy-square, Professor in the Royal College of Chemistry. Improvements in preparing colouring matters for dyeing and printing.

Dated May 23, 1863.

1294. J. A. Pickering, Heath-cottage, Oatlands Park, professor of music. Improvements in covers or capsules for bottles, jars, and similar vessels.

1295. W. Cormack, Manchester, chemist. Improvements in the distillation of coal tar, tar oil, resin, resin oils, all hydro-carbons, petroleum, or other mineral or vegetable oils and spirits derived therefrom.

1296. S. E. Rosser, Northumberland-street, Strand, warming and ventilating engineer, and J. G. Jennings, Palace-road, Lambeth, sanitary engineer. Improvements in chimneys, fire-places, stoves, and flues, for warming and ventilating apartments.

1297. J. S. Bickford and G. Smith, Tuckingmill, Camborne, Cornwall, safety fuze manufacturers. A certain new manufacture for firing explosive compounds.

1298. W. Hoey, Great George-street, Bermondsey, tanner and currier. The preparation of a fluid for renewing the surface of japanned and enamelled leathers and cloths.

1299. J. Hopkins, Chapel-street, New Basford, Nottingham, lace maker. Improvements in points and in crossings used on railways and on tramways.

1302. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in the manufacture of bells, and of resisting and non-cutting tools. (A communication.)

1303. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in safety garments. (A communication).

1305. G. Smith, Fenchurch-street, merchant. Improvements in lamps for burning hydro-carbon oils. (A communication.)

Dated May 25, 1863.

1306. J. Hesford, Cunliffe-street Works, Bolton, millwright and engineer. Improvements in machinery and apparatus for stretching and drying cotton and other fabrics or materials.

1307. W. Muir, Britannia Works, Manchester, engineer and machinist. Improvements in machinery for cutting sugar, and for assorting the lumps when cut.

1309. H. A. Bonneville, 24, Rue du Mont Thabor, Paris. Improvements in the construction of carriages. (A communication.)

1310. P. Leprovost, London street, Paris, civil engineer. Certain improvements in carriages and vehicles for railways and other roads.

1311. E. Hunt, Glasgow, patent agent. Improvements in posts or pillars for fences and gates. (A communication.)

1312. G. Köttgen, Barmen, Prussia, manufacturer. An improved binding to be used for trimming woollen cloth garments.

1313. H. B. Girard, 11, Rue du Conservatoire, Paris, chemist. Improvements in the heating of every industrial and private apparatus by means of the oxygen and hydrogen gases combined and obtained from the decomposition of water.

1314. T. Spurrier, Moseley, Worcester, gentleman. Improvements in the manufacture of ornamental metal cylinders.

1316. C. Hare, Norwich, chair manufacturer. Improvements in reclining and easy chairs.

1317. R. Hayward, Wapping, wine cooper. Improvements in apparatus for bottling liquids or for drawing or letting off at the same time liquids from several different casks or vessels.

1320. W. Clark, 53, Chancery-lane, engineer. Improvements in apparatus for ruling paper and other materials, either alone or in combination with typographical or lithographical printing. (A communication.)

Dated May 26, 1863.

1321. A. Haley, Frome, Somerset, machinist. Improvements in jacquard looms.

1322. J. Munro, Tillanburn, and R. Scott, Cambusnethan, Lanark, engineers. Improvements in apparatus for boring, mining, and excavating, or cutting; in motive power engines; and in pressure gauges.

1323. E. K. Dutton, Stretford, mechanical engineer. Certain improvements in apparatus, called "gins," for cleansing seed cotton.

1324. M. Henry, 84, Fleet-street, patent agent. Improvements in apparatus for raising, forcing, and moving fluids. (A communication.)

1325. J. Buckingham, Launceston, Cornwall. Improvements in ploughs.

1327. W. E. Newton, 66, Chancery-lane, civil engineer. Certain improvements in machines for separating the fibre from the flesh of plants. (A communication.)

Dated May 27, 1863.

1329. W. Clark, 53, Chancery-lane, engineer. Improveprovements in offensive and defensive arms. (A communication.)

1330. A. Bastow, Bradford, York, manufacturer. Improvements in looms for weaving.

1331. H. C. Coulthard, Park Ironworks, Blackburn, engineer. Improvements in blast engines.

1332. H. J. Kennard, 36, Great George-street, Westminster. Improvements in the construction of wrought-iron cylinders for piers or piles to bridges, viaducts, or for other foundations or structures where the sinking of cylinders is required.

1333. C. Gammon, 9, Cloak-lane, City, gentleman. An improved spring fastening.

1334. W. Palliser, Capt. 18th Hussars, Dublin. Improvements in projectiles for ordnance.

Dated May 28, 1863.

1336. W. I. Ellis, Vulcan Foundry, near Warrington, engineer. Improvements in steam boilers.

1338. G. Gore, Birmingham, consulting chemist. Improvements in gas burners and in gas furnaces.

1340. H. Cartwright, Dean Broseley, Salop, gentleman. Improvements in apparatus for steering vessels.

1342. T. Richardson, Newcastle-upon-Tyne, chemist, and R. Irvine, Musselburgh, Mid Lothian, manufacturing chemist. Improvements in treating the waste liquor obtained in the preparation of esparto grass.

1344. T. H. White, Piccadilly, accoutrement maker. Improvements in hats, caps, and other coverings for the head.

1346. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in paddle wheels. (A communication.)

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated May 28, 1863.

1341. C. F. Baxter, Boston, U.S. A new and useful hollow elastic stopper for bottles, jugs, and other similar vessels.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1200. H. Wilde. Electro-magnetic telegraphs.

1210. T. Lawrence. Drying, dressing, brushing, waxing, and finishing fabrics.

1248. C., J. B. C., jun., and G. Barnard. Lawn mowing and rolling machines.

1256. A. Parker. Saving from destruction by fire persons and property in houses, buildings, and ships, and also for ventilating ships. (A communication.)

LIST OF SEALED PATENTS.

Sealed June 5, 1863.

3286. R. A. Brooman.
3307. W. Inglis.
3313. D. Chalmers.
3317. E. Toynbee.
3318. I. Spight.
3367. A. Albini.
3452. W. Clark.
3455. J. Swainson.

Sealed June 9, 1863.

3322. R. Clark.
3330. J. Gaskell and H. Walmsley.
3338. E. Thorold.
3339. C. Corbet.
3392. S. G. Lister.
3397. W. L. Longridge.
3429. S. Russell.
3442. R. Lakin and J. Wain.
3453. C. F. Varley.
3477. J. E. Carter.
81. W. H. Moreland and J. Chappell.
99. W. E. Newton.
256. W. Clark.
308. W. E. Newton.
412. J. Morgan.
501. G. Davies.
654. Sir A. Keller.
717. G. De Laire.
765. T. G. Grant.
1020. R. Lavender.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

1357. C. W. Lancaster, J. Brown, and J. Hughes.
1373. C. Senior.
1386. F. H. Wenham.
1388. C. Stevens.
1391. C. Hadfield and W. A. Attkins.
1394. W. McI. Cranston.
1406. M. Jacoby, J. Redgate, and J. Stones.
1408. G. A. Waller.
1410. G. Kane.
1412. A. A. Croll.
1425. J. Combe.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

1310. E. Marsden.
1358. W. E. Wiley.
1387. J. Combe.
1468. G. Gurney.
1473. H. H. Vivian, B. G. Herrmann, and W. Morgan.

The *Daily Telegraph* of March 31st, in its description of Benson's Great Clock, says: "it is a triumph of ingenuity." —Benson's new show-rooms contain clocks designed by the first artists of the day, and include clocks for the drawing-room, dining-room, bedroom, library, hall, staircase, bracket, carriage, church, turret, railways, warehouse, counting-house; with musical, astronomical, and every description of clock, from the plainest to the highest quality of which the art is at present capable. Church and turret clocks specially estimated for. Benson's illustrated pamphlet on clocks and watches (free by post for two stamps) contains a short history of clock and watch making, with descriptions and prices; it acts as a guide in the purchase of a clock or watch, and enables those who live in Scotland, Ireland, Wales, the Colonies, India, or any part of the world, to select a clock.—J. W. Benson received a Prize Medal and Honourable Mention. 33 and 34, Ludgate-hill, London. Established 1749.

LONDON, FRIDAY, JUNE 19, 1863.

STEAM ON COMMON ROADS.

Some inventions spring at once into public favour; others creep into it at a snail's space. The introduction of steam as a means of locomotion on our highways seems to follow the latter rule. Just a century ago, the first locomotive with regard to which we possess any reliable data, was constructed by Louis Cugnot. The success of this little machine was sufficiently great to demonstrate the fact that animal power was no longer necessary to locomotion. Long after Cugnot came Handcock, Gurney, Dance, and many others, who constructed steam omnibuses and carriages of various kinds with more or less success; and having each developed some novel principle or contributed some new fact, have died, and, with their engines, sunk into comparative oblivion, leaving the subject, as far as general adoption goes, to all intents and purposes as little advanced as they found it. Once more revived, some few years ago, it has since received sufficient attention to warrant the expectation that at last fair progress was really being made. The Patent Office again became the receptacle of invention after invention, all having for their object the development of the comparatively new principle. Government roused itself; the necessity of traction engines to the economical working of dockyard transport, was regarded as a proved fact; and, after many, trials a couple of "Boydill" engines found their way to Woolwich, amid a flourish of trumpets from those daily papers which considered themselves the friends of progress. Companies were established to introduce the engines of other makers. A glorious future seemed at last to dawn on the steam horse; and Mr. Punch's millenium, when every gentleman would possess his own private steam carriage, seemed to have nearly come. None of these expectations, formed three or four years ago, seem, however, to be fulfilled; instead of advancing in public estimation, the warmest advocates of the road locomotive must admit that its more extended adoption is as far off as ever, and that it sinks rather than rises, in that estimation which is the life-blood of every novel invention. Government offer their engines to the highest bidder. In other directions, we find steam locomotives offered for sale with the highly suggestive recommendation that they can easily be converted into stationary engines—a fact apparently deemed necessary to secure a purchaser.

Convinced as we are that by steam locomotion on common roads, many important prospective benefits are held out both to England and her Colonies, we think the investigation of the causes which have led to the partial failure of the system are well worthy the careful attention of our engineers. On the closest examination we fail to discover any defect in the principle on which success depends, which is, of course, just the same as that which has proved so eminently successful on our railways. To cause the revolution of a pair of driving wheels, which, laying hold of the road as a fulcrum cause the locomotion of the whole machine, is no very abstruse problem; and even though it were, it has met with a successful solution so long since, that no matter what our forefathers might have found it, we, their sons and grandsons, have no reason to complain. But, not content with the accomplishment of this feat, our sapient inventors have invested the question with a thousand difficulties which never existed; and with that usual disregard for the commercial success of their inventions which the inexperienced usually display, they have converted a really simple machine, into one so complex in its character, that expense and want of durability follow as a matter of course. The resulting depreciation in public opinion is, unfortunately, not confined to one particular class of engine; for if that class has been brought prominently forward it is soon regarded as a type of the entire system, which, of course, shares in the injurious consequences.

We do not hesitate to assert that in the endeavour to make the road locomotive perform too much, will be found one of the primary causes of that want of commercial success which has hitherto retarded its more general employment. Stephenson and his compeers were satisfied if their engines did one thing well; and by concentrating all the energies of the machine on the one object in view, they enabled it to attain the most satisfactory results. But modern inventors are not satisfied with the locomotion of their machines on hard roads, as Stephenson was; but attempt, in addition, to make it perform many other offices as well—in fact, nothing is too much to require from a traction engine, which, in the hands of some engineers, far more resembles the contents of a factory out for a walk, than a machine which should be alike distinguished for beauty of form and simplicity of design. We thus find them professing to drive all sorts of machinery by means of straps, as well as to possess the power of traversing the surface of swamps and moors at a moderate pace, while high speeds can be attained on good roads! The highest expectations are naturally indulged in by those whom the sanguine inventor can influence in the slightest degree; disappointment follows; and as we have already said, not only an individual machine, but an entire principle, undergoes condemnatory remarks, and comes to be regarded as a delusion and a snare.

The public is always ready to expect great things from an invention which has been proved capable of being worked out to a satisfactory result; and they have in this spirit doubtless, formed extravagant ideas of the capabilties of the machines we speak of—a result due in no small degree to the highly coloured paragraphs met with every now and then in local newspapers. We have heard of a gentleman—one, too, who pretended to some knowledge of mechanical engineering—who wished a firm to contract with him for the building of an engine which should attain a speed of fifteen miles an hour, unloaded, on a level road; should be suited to the traversing of grass land, with heavy loads of farm produce; should pump, saw, or thrash, and provide accommodation for two or three ladies in front, after the fashion of the Earl of Caithness's little pleasure carriage: we believe such instances are by no means rare. A London coachmaker would scarcely feel pleased by an order for a family barouche which should be capable of transporting farm produce to market. Engineers enthusiastically undertake to perform these constructive feats; prudent coachmakers are satisfied by building and selling the simplest machines they can contrive, well knowing that these alone pay.

Not content with the legitimate employment of steam power on our generally excellent highways, we find traction engines fitted up with the most costly appliances to enable them to traverse fields and lanes, where they never should attempt to go. It is simply absurd to expect them to work successfully on soft bad roads. Endless railways, shoes, and all such devices only add to the complication of the machine without serving any good purpose whatever. Even if they prove themselves mechanically successful, which to do them justice, at extremely moderate speeds they usually do, we must still recollect that steam power in England, at least, never can compete commercially with horses, in situations which render the use of such expedients necessary. It is on hard, moderately level, turnpike roads that we must expect the success of steam transport, not over bogs and morasses. In our Colonies the case is different; there roads are few and bad, and the engine may have to traverse the face of the country. There is no mechanical difficulty in this, the commercial difficulty must, of course, be a mere question of the comparative expense and efficiency of animal labour.

Another extremely injurious element is to be found in the slow average speed to which engines suited to the transportation of heavy loads have hitherto been limited. A speed of two or three miles an hour is too little when long journeys have to be performed, though it may answer well enough for short trips. The time lost in getting water is considerable, and should be provided for by the power of attaining a fair speed on favourable portions of the road, as in descending moderate hills. Engineers frequently propose to confer this power by providing cylinder and boiler room enough to attain a speed of even nine or ten miles an hour. We have little fault to find on that head; but we must recollect that, no matter what the facilities for the production of steam may be, a high speed may be quite beyond the powers of the machine, as far as its abilities to resist the injurious effects of rough roads are concerned. Shoes and endless railways, too, can never be persuaded to work quietly or satisfactorily at fair speed; and this is yet another reason why they are likely to prove injurious rather than beneficial to the entire system.

Smooth wheels, with sufficiently large bearing surface, provided by considerable breadth of tyre, moderately loaded; simple mechanism, unburdened with cranes, winding drums, &c., &c., and, above all, good and flexible springs, are absolutely essential to the high speeds which should be attained on suitable portions of the road, in order that ample margin may be left for delay in ascending steep hills, taking in water, and the other delays incidental to a moderate journey.

Let traction engines surpass horses in the speed with which they transport goods or merchandize, as well as in the actual power of moving enormous weights, and we find the chances of their commercial success trebled; but let each of those duties be performed by separate machines, if any complication is to be induced by the attempt to perform both with one engine. It may, indeed, be urged that suitable gearing enables speed and tractive power to be used interchangeably; but the extra tractive power is seldom available from want of adhesion, unless we resort to weights far too great to be recommended for comparatively high speeds. Express engines are not employed to draw goods trains on our railways.

That machine is most perfect which is most simple; and from simple arrangements of steam machinery can we alone expect the perfection of a system which possesses advantages sufficient, under proper management, to lead to ultimate success; but it must be borne in mind that in the road locomotive we have a nice arrangement of machinery, unavoidably compelled to perform its work under the most trying circumstances to which machinery can be exposed. Their successful construction, therefore, renders necessary a special knowledge of all their requirements, which nothing but practical experience can give. Hardly any other machine demands so much attention to minute matters of detail, which the theorist is certain to overlook; and of one fact we may rest certain, that all attempts at complicated "improvements" in railroad locomotives have failed and will fail, that their present success is mainly due to their beautiful simplicity, and that our road locomotives must conform to somewhat similar rules and principles, before we can expect that peculiar mechanical perfection, on which commercial success waits as a handmaid.

CHAIN CABLES AND ANCHORS.

It is not improbable that the Bill lately introduced in Parliament by Mr. Laird, for enforcing a test of the chain cables and anchors used in the merchant service, will be included in the "Massacre of the Innocents," that generally takes place at the end of a session. Bills for the same purpose have been previously brought before Parliament, but without being carried. This time, however, the misfortune is not so great; and, indeed, it may almost be doubted whether a compulsory Act is required at all; for since the latter end of November last, Lloyd's have taken the matter into their own hands, and they undertake to prove, for a small sum, any chain cables and anchors brought to them for that purpose. Every ship, however, is not classed at Lloyd's; and reliable chains and anchors are necessarily of such importance to the safety of those "that go down in ships on the deep," that it would perhaps be best if every large seaport were provided with a public testing machine.

An excellent description of the proving-house of Lloyd's Committee, erected last year by T. M. Gladstone, C.E., in the New-road, Poplar, near the West India Docks, will be found in our number for May 15. The description was extracted from a contemporary. Having lately inspected the works in question, we are enabled, by our own observation, to completely endorse the laudatory observations of our contemporary on the mechanical arrangements of this establishment, designed and erected under the superintendence of Mr. T. M. Gladstone. More than 1,000 tons of chains and anchors have been already tested at the Poplar Proving-house since the beginning of December last, and there is a daily progressive increase in the number of cables tested. No less than 117 tons of cables, and 12¾ tons of anchors, were tried last week. As may well be imagined, Mr. Gladstone can show quite a "Museum of Morbid Anatomy" of broken links—a collection containing specimens of the most varied structure and quality of iron. In the great majority of cases a link gives way in the welding; this happens, according to Mr. Gladstone, in nine cases out of ten. The welding is generally made at the side of the link; but when the link breaks in sound iron, one of the ends is almost always sheared out and torn away. As a rule, all chains above 1 in. are welded on the side; the exceptions that occur are through motives of mistaken economy. We noticed a 1⅞ in. link (evidently made of imperfectly-puddled iron), which broke at only 45 tons; the Admiralty proof for this diameter of link is 63¼ tons. The breaking strain of good cables, made of No. 3 iron, is about 25 to 28 tons per square inch; this strength appears to get reduced by about one-fifth by being put into the form of the cable; the specimen we noticed, however, thus broke at little more than 8 tons to the square inch. Each cable is of course measured before being brought under the strain of the press, and its permanent elongation is noticed and marked on the certificate. On an average, cables appear to stretch permanently 6 ft. in 90 ft. Mr. Gladstone has a pressure indicator in his private office on the first floor, by which means he has a constant check on what is going on down below. This indicator consists of a common Schæffer's gauge, under the pressure of water. It might be objected that it would be difficult to identify a chain that had been tested, and that the certificate given with each tested chain might be used for another which had not undergone the test; or again, that an unprincipled manufacturer might obtain an unlimited number of certificates from the same chain, with the intention of applying these false certificates to untested cables. The system adopted at the Proving-house completely meets these objections. Each cable is stamped with the date of the test, and in addition there is an ingenious system of private marks, by which the ship surveyors can always identify the chain with its certificate. The position of the marked link is determined by a secret formula which takes the length of chain into account, and any alteration, through accident or design, in the length of the chain, must be marked on its certificate.

The adoption of this organized system on the part of Lloyd's Committee has, no doubt, in a great measure resulted from the evidence adduced before the Select Committee appointed by the House of Commons, in 1860, to inquire into the manufacture of anchors and chain cables for the merchant service. As stated by the Committee, the evidence of the witnesses showed at the outset that losses of chain cables and of anchors by breaking happened very rarely in Her Majesty's Navy as compared with the merchant service, in which disasters are continually occurring from deficiencies in this part of a ship's tackle. A well-known instance of this difference between the two services, that will recur to the minds of most of our readers, was shown in the great hurricane that caused such a devastation amongst our transports in the Black Sea in 1854. The majority of the merchant ships parted with their cables, and were drifting about and being dashed to pieces against the Crimean coast, while there was not one ship in the Royal Navy but rode out the storm in safety. Sir Deans Dundas, then commanding the fleet, addressed a public despatch to the Admiralty, in which he reported the perfect efficiency of the chain cables supplied to Her Majesty's ships.

The system of testing was first established by the Admiralty in 1833; but previously to that date a certificate was sent by the contractor with his cables, proving that they had been tried on his premises. The chief clerk of the Store-office, Mr. J. R. Clark, in the course of his evidence before the Select Committee in 1860, also stated that chain cables were first introduced into the Royal Navy in 1810 by the then Lieutenant Samuel Brown, who patented his invention in 1808. It may be stated that an iron chain weighs, on an average, 2½ times as much as a hempen rope of the same strength, while the diameter of links is about 3-10ths of that of a similar rope. A hempen rope is thus easier to lay out than a chain cable, but the smaller space taken up by cables has allowed a reduction of the tiers of a line-of-battle ship.

There can be little doubt as to the utility and, indeed, absolute necessity of a test for such wrought-iron work as cables and anchors. It is impossible for the most practised eye to ascertain whether a weld be good or bad; a little extra hammering will soon cover up and hide any deficiency in that respect. In the same way, the quality of the iron may have been originally good, but the material may have been burnt by unskilful forging. A famous physician is said to have once expressed a wish to possess the ability of walking down his patents' throats with a lantern in his hand, and to thus form a correct diagnosis of their state of health. It is just as impossible for us to get into the inside and at the ultimate structure of iron, and so we must content ourselves with extraneous trials. We would thus advocate a universal system of compulsory tests for all ships' cables and anchors, to be conducted under the supervision of the Board of Trade. It was in evidence before the Committee formed in 1860 to examine into the question, that, during a period of five years, of the cables sent to the Liverpool testing machine, 82½ per cent. were imperfect cables. Now, if the test be not compulsory and be not universally applied, it is not improbable that rejected and imperfect cables will find a market amongst the ignorant or the unprincipled.

It has been stated at different times that chain cables are injured by the tests applied. In order to prove that no injury is brought on cables by testing, Mr. William Willcocks, the Master Smith at Woolwich, gave the following interesting account of an experiment made by Government to ascertain the truth of the case. A length of 2¼ in. cable, the proof of which is 91⅛ tons, was tested in the usual way. The chain was made by Hawks and Co., in 1843. "It was subsequently tested to the proof strain twice, and then broke at 119·5 tons; after which, being shackled together, it was tested to proof strain twice; then to 119·5 tons; then to 120·5 tons; then to 223·3 tons; then to 126·625 tons; then broke at 123·125 tons. It was then shackled together, and proved up to 127·5 tons; then to 134·25 tons; men exhausted; then broke or crushed a stay-pin, and broke the link thus unprotected at 133 tons. I beg also to state, that a length of 2⅛ in., the proof strain for which is 81¼ tons, was afterwards broken at 100·75 tons; then to 109·25 tons; broke at 109.75; again shackled together, and broke at 108 tons; then at 110 tons. The second piece ultimately bore at the 13th trial 122.625 tons." In answer to a question by Admiral Duncombe, Mr. Willcocks stated that he had never known an instance of a chain cable, often being tested, breaking at a much lower strain than that it had undergone during the test. The experiments we have referred to were continued, and a length of 1¾ in. was tried, the proof strain for which is 55⅛ tons. At the sixth trial, this broke at 83·625 tons. The second piece of the same size was also tested, and it broke at the eighth experiment, also at 83·625 tons. "A length of 1 in. cable was also tested, the proof for which is 18 tons; ultimately it reached a breaking strain at the ninth trial at 26·375 tons. The second piece of the same size broke first at 15·5 tons, at a very weak part of the swivel, being a quarter of an inch under the required size; the pieces were, as before, shackled together up to seven times, when it broke at 26·75 tons."

These trials were evidently made on iron of a very high quality. It will be apparent, on reflection, that a cable might be made so as just to stand the proof, and yet be of a bad material. In such a case the Admiralty test of 630 lb. per circular ⅛ in., or 11·46 tons to the square metre, might materially injure the structure of the iron. The plan to partially meet this difficulty would be to occasionally break a link in the chain, so as to examine the quality of the iron, and this was, in fact, proposed by several witnesses before the Committee of 1860; amongst others by Mr. T. M. Gladstone. It is worthy of note that Mr. William Pope, the Surveyor for Lloyd's at Liverpool, during the last twenty years, objected to the Admiralty test as being too high, and apt to cripple inferior qualities of chain. He proposes that cables should be subjected to only half the usual Admiralty test, in order to try the welds, while a few links of every cable, indiscriminately chosen, should be broken by the testing machine in order to ascertain the quality of the iron used in the cable. Iron, unfortunately, varies so much in quality, that applying the same test to all kinds alike certainly seems attended with some danger. This system would, however, evidently cause great expense to the manufacturer.

Another important question in relation to this subject, regards the re-testing of cables and anchors after being some time in service. Mr. W. Macdonald, the Manager of the Liverpool Corporation Testing Machine, and Mr. G. T. Thomson, a pilot of twenty years' standing, in the employ of Mr. Wigram, the eminent ship-builder and owner, both recommended this operation. Mr. Thomson would make it imperative to test every cable after being in use for six years. In addition to the usual deterioration of a cable through wear, rust, exposure, and accident, its material undoubtedly undergoes a change, losing its fibrous texture and assuming one of a crystalline character. The laws governing these molecular phenomena are as yet obscure, and have not been fully investigated, but the results are undoubted and have been noticed by most practical men. A familiar instance of this change is found in crane chains; and railway carriage axles undoubtedly get crystallized in course of time. Mr. Gladstone, in the course of his evidence before the Committee, alluded to the subject very fully; he proposed to obviate this deteriorating influence on the strength of cables and anchors by annealing them before being re-tested.

STEAM DOMES FOR LOCOMOTIVES.

Our engineers still seem to regard the steam dome as an indispensable adjunct to the locomotive; at least, few or none are built without them. Indeed there seems to be rather a tendency to increase their size and over estimate their importance, due in some measure, perhaps, to the increased adoption of the flush boiler, which is not considered to be so well suited to the supply of dry steam, as those which have the outside fire-box shell considerably raised above the cylindrical portion of the boiler. The advantages held out by the dome are, however, more than doubtful, and can scarcely compensate for the additional weight and expense incurred by its use, although it is urged that without it considerable difficulty is always experienced from priming. This, at best, but proves that such contrivances may be employed as a means of repairing faults of design in other departments of the engine, and by no means demonstrates as a fact that they are actually indispensable, or indeed, deserving of general adoption. In many engines we find them either omitted altogether without at all impairing the efficiency of the machine, or of such small size that they bear no comparison with the huge edifices recently introduced. Bury scarcely ever used the steam dome in its present form. True, he placed an immense hemispherical affair over his fire-box; but this, in all cases, formed part of the external shell, and was merely a means of supplying steam room. Forester's small domes were placed on an outside fire-box shell, the top of which was already raised 12 or 14 in. above the barrel. Such domes did not contain a cylinder full of steam, and were only intended to permit the elevation of the steam-pipe to a good distance above the water level—a plan since carried out by other makers with good results. Stephenson, it is true, did of old, as his successors do now, pretend to the extension of steam room by the use of large domes, though the advantages gained from them in that way can be realized by far better arrangements.

All things considered, if proper care be taken to secure perfect circulation in the water, we consider them unnecessary and injurious. It is not very easy to make a good dome; its welding is a job which requires both skill and care; and the difficulty experienced to some extent in making up the joint between it and the boiler shell, together with the cost of the outside ornamental casing, constitute it a very considerable item of expense. Its connection too with the boiler, must in some degree weaken the latter by rendering an aperture of considerable size necessary. Although a manhole is always requisite to permit the proper inspection of the interior of the boiler, it does not follow, as a matter of course, that this is best closed by a steam dome. The contrary is the fact; for the dome should be placed forward where the ebullition is least; while the proper situation for the manhole is, undoubtedly, over the fire-box—indeed we find one there as often as not; while a steam dome is fixed near the chimney, and supplied with an amount of internal apparatus, sufficient to prevent its use as an entrance to the barrel.

A very slight increase in the diameter of a boiler, will easily provide as much additional steam room as a very large dome can supply, and provides it, too, without extra expense or trouble, or weakening the boiler to any appreciable extent, not so much indeed as a large hole in the shell can do. Still some engineers seem to consider it necessary that the steam should be drawn from a point considerably above the water level; a conclusion scarcely borne out in practice, as we find very many engines, both here and in America, getting on very well without domes, and supplying steam to the cylinders dry enough to cause no complaint.

Aware of the objections attending the cutting of a large aperture in the boiler shell, many makers content themselves with drilling a great number of small holes in it, just under the dome. We have always found this remedy worse than the disease; for not only is a separate manhole still necessary, but in addition the perforated plate defeats the object in view, by inducing priming to a very considerable extent. This is one of those phenomena which no amount of theoretical consideration could teach us to guard against, although practical experience demonstrates the fact plainly enough: water once gaining access to the interior of the dome, as it is sure to do, is unable to return to the boiler, because of the rush of steam through the holes, and consequently finds its way, often in considerable quantities, to the cylinders.

All things considered, the best plan seems to consist in placing a small dome, when such a thing is considered indispensable, over the fire-box communicating with the interior of the boiler, by means of an aperture large enough to admit a man. The steam pipe should rise nearly to the top of the dome, and terminate in a large flared or trumpet-shaped mouthpiece, nearly as large as the diameter of the dome will admit, and finished off to an edge all round; over this should be fixed a hollowed plate, with the convex side up, of the same diameter, so that its edge and that of the trumpet-mouth may coincide, and not be more than an eighth of an inch or so asunder. This arrangement will be found to prevent, to a great degree, the entrance of water into the pipe, and is extremely simple, and easily fitted.

A flush boiler, however, undisfigured by a dome, is, in our opinion, absolutely necessary to that beauty and simplicity of appearance which is such a characteristic of the best class of locomotive. Dry steam may easily be obtained by the use of one or more perforated pipes traversing the upper part of the boiler. By diffusing the draft of steam, and not permitting it to concentrate at any particular place, priming may usually be best avoided, especially if ample water-space is provided round the fire-box as well. If this last is constructed with sloping sides, it adds, not only to the durability of the plates of which it is composed, but enables the boiler to supply dry steam even with the heaviest loads. Priming is far more due to defective circulation than to anything else; and with proper attention to the means of providing for this in the best manner, and by the use of perforated pipes, we see no reason why the unsightly and expensive dome may not be banished from our engines.

THE BESSEMER PROCESS IN FRANCE.[*]

The manufacture of steel under M. Bessemer's patents is still regarded by our Gallic neighbours with astonishment, which our ironmasters have long ceased to feel. The French steel-makers regard the whole process as little short of miraculous, and still look on its more extended introduction with a doubt and hesitation which is perhaps a principal cause of the slow progress made by the process towards more general adoption in France; indeed, it appears that there is but one factory in the empire, that of Jackson and Co., at St. Seurin, where the manufacture of Bessemer-steel is carried on, on anything like a large scale.

These steel works are advantageously situated on the river d'Isle, by means of which boats can deliver coal and iron on the wharfs belonging to the factory. A fall of water equivalent to 200-horse power gives motion to two large and three small water-wheels, which supply the necessary power for driving the various machines.

The founder of these works, Mr. William Jackson, grandson of the Jackson who introduced the Huntsmann process for making cast steel into France, finding a mill-site in so favourable a situation, for sale, purchased it, resolving to establish his hereditary manufacture. Soon joined in his enterprise by his father, he established some cementing furnaces, coke ovens, &c., and commenced the manufacture of cast steel on a small scale. Afterwards, availing himself of the power bestowed by the waterfall, he erected tilting hammers, rolling trains, and all the other machinery necessary to supply steel in large quantities. In 1856, hearing of the success of Bessemer's process in England, he erected, under licence, an apparatus capable of converting 700 kilogrammes of cast iron into steel at a time. Having experimented on an extensive scale for five years with almost unvarying success, he constructed the present apparatus, which easily converts 3,000 kilogrammes of cast iron at one operation.

---

[*] Les Grandes Usines, Acieries Jackson and Co. Usine de Saint Seurin, Appareil Bessemer.

In the lower story of a large building are placed, facing each other, two large converting vessels, or as the French style them, *cornues*, formed of thick iron plates riveted together and lined with fire clay. These vessels turn on trunnions, so as to easily assume the different positions required during the work of conversion. Between them there is a circular area surrounded by a little trench, in which, half-buried, are placed the moulds to be filled. From the centre of this circular space rises a hollow pillar, some three or four feet high, carrying a forked lever at right angles, which can be raised or lowered at will by water pressure acting on a piston within the pillar. Within the fork of this lever is grasped a ladle, lined inside with fire clay, easily moved by an iron handle passing through the horizontal part of the forked lever; this ladle is pierced with a hole in the lower part, easily stopped or unstopped at will by a plug of fire clay, formed on the extremity of an iron bar, which can be raised or lowered as desired.

When the converting vessels are vertical, they present their greatest convexity towards each other, while the aperture at the upper end is directed into the side of a chimney or flue. Into the lower part of each, opens seven tuyères, each pierced with five holes. These tuyères communicate with the blowing cylinders by a tube, passing through the trunnions. The blast is produced by a steam-engine, the boiler of which is heated by the waste heat from the furnaces where the iron which is to be converted is melted. The selection of this iron is the most important consideration for the steel manufacturer. At St. Seurin good English pig is most generally employed—a suggestive fact for our own steel-makers. Mr. Jackson, in the course of his experiments, has tried Swedish, Perigord, Bretagne, and Commentry pigs. Of all the French irons, the last has given the best results.

The iron is melted in reverberatory furnaces, and poured into the converting vessels, previously heated by coke fires lit within them. When half-full, the blast is put on, and the converting vessel raised to a vertical position from the partially horizontal one it assumed while receiving its charge of molten iron. The force of the blast prevents the iron entering the tuyères. The combustion of the carbon in the iron is so intense that it bears no comparison with anything else. The flame escaping into the chimney is at first red, and attended with an immense number of sparks. After about twenty-five minutes it diminishes in intensity, when the person directing the operation causes the mouthpiece of the converting vessel to be lowered once more. A ladleful of a peculiar mixture of different irons is then poured into the converting vessel. In this mixture the whole secret of success seems to reside. This it is which converts into good steel the molten metal, which without it would be worthless. The apparatus being immediately raised once more, the blowing is recommenced, and continued for a very few minutes, when the operation is terminated—cast-iron has become steel.

The contents of the converting vessel is then poured into the ladle, which, guided and supported by the forked lever, can be emptied into the moulds which surround the central pillar on which the supporting lever turns horizontally. When each mould is full, the aperture in the bottom of the ladle is closed, and the workmen pass on to the next, repeating the process till the ladle is empty. By this means Mr. Jackson easily produces ingots of 200 kilogrammes, and large castings of 1,200 kilogrammes. By using both converting vessels at once, he easily produces castings of 2,500 kilogrammes to 3,000 kilogrammes. The yield of these works is, on an average, 5,000 kilogrammes per day—1,000 kilogrammes being rather less than an English ton.

"THE ENGINEER'S POCKET-REMEMBRANCER."*

Amongst the many "Engineer's Pocket-books" now bidding for the favour of the members of our profession, this particular specimen seems well-deserving of patronage. The above title shows the intended scope of the compilation, and the book appears to redeem the promise as completely as is possible in a work of this character. We say "compilation," although several of the formulæ are evidently original. The formulæ are also in all cases expressed by verbal rules, for those who are unaccustomed to algebraical notation. The low price of the book (5s. 6d.) places it within the reach of most men.

The ramifications of engineering practice are already so extensive, and the separate specialities are getting so fully developed, that it is doubtful whether any "Pocket-book" could be compiled to completely suit the wants of every branch of the profession. Take, for instance, agricultural engineering, which we might already call a separate branch. Except the general formulæ applicable to all engineering practice, no other aid is afforded by any Vade-mecum as yet published, to any individual whose practice lies in this direction. The ultimate result will probably be, that a special work will be required for each class of engineers.

MAGNESIUM.†

The following is an abstract of a very interesting article by M. Sonstadt, which has appeared in *Weldon's Register*. M. Sonstadt has devoted considerable attention to that department of chemistry which deals with the preparation of the comparatively new metals, and has recently patented a new process for the manufacture of magnesium on an extended scale:—

In the history of the world's "metallurgic" period, to the present time, there has been a nice gradation as to the class of metals wrought,—those metals which occur native, or in an easily reducible state, such as gold, silver, copper, tin, iron, and mercury, having been known since very remote periods; while the somewhat more difficultly obtainable metals, as arsenic, antimony, and zinc, were not worked, so far as each metal is distinctly and separately concerned, until comparatively modern times. Not till the nineteenth century were any metals obtained on a commercial scale which were not obtainable by such simple processes as washing, roasting, and reducing the ore by the aid of heat in contact with charcoal or other carbonized matter, with the addition only, in some cases, of limestone, or of fluor-spar, for fluxing.

As the magnificent new dyes obtained from coal-tar products primarily owe their discovery to the purely scientific investigation of the coal-oils by Faraday some thirty years before, so chemical metallurgy may be said to date from the time when Sir Humphry Davy proved the existence of metallic bases in certain alkalies and alkaline earths. Davy isolated those metallic bases only in very small quantities, and by means only of the most powerful galvanic battery then in existence. Brunner afterwards obtained potassium by the ounce, by heating hydrate or carbonate of potassium in contact with very finely divided and intimately mixed charcoal, in a gun-barrel, or in a mercury bottle, with tube and condenser attached. Until Deville conceived the happy thought of introducing aluminium to the arts and manufactures, potassium, costly as it was, was far less costly than sodium: a given weight of the latter, nevertheless, being able to do more chemical work than the same weight of potassium, inversely to the proportion of 23 to 39, since such are the combining proportions respectively of the two metals. Influenced mainly by this consideration, Deville addressed himself earnestly to the task of cheapening sodium, the cost of sodium being the index to the cost of aluminium, since the latter is obtainable from some of its comparatively inexpensive compounds by the inexpensive process of the reaction upon them of sodium at a red-heat. Deville soon found that sodium could be obtained much more readily than potassium. When dried carbonate of sodium (from the crystals) is intimately mixed with charcoal, or coal-dust, and a little carbonate of calcium, the mixture placed in an iron bottle (such as mercury is imported in), with tube and receiver adapted, and the bottle heated in a furnace to near whiteness, sodium distils over abundantly, and drops from an aperture in the receiver into a vessel, containing naphtha or bituminous oil, placed to receive it. In this process, the sodium is eliminated in an atmosphere of carbonic oxide, from which,—singularly enough, as no such reaction takes place with carbonic acid,—sodium reduces carbon with liberation of oxygen, and, of course, the loss of metal by the formation of oxide of sodium. Hence the use of the carbonate of calcium, which at a high heat liberates carbonic acid gas, and this serves as a carrier to the sodium vapour, conveying it rapidly to the receivers, where it is condensed before any notable quantity can be lost by the reaction with the atmosphere of carbonic oxide in which the sodium is generated. Sodium may be obtained on almost any scale by what is essentially the same process, long malleable-iron cylinders being substituted for the iron bottle.

Aluminium is obtained by the action of sodium at a red-heat upon the double chlorides, or fluorides, of aluminium and sodium. Sometimes the chloride of aluminium is vaporized, and the vapour brought into contact with sodium vapour, when aluminium is liberated. In any case, the sodium simply replaces the aluminium by reason of its stronger affinity for the halogen with which the aluminium was combined. Precisely similar is the reaction of sodium with certain salts of magnesium and of silicium, both of which are displaced by sodium from their combination with chlorine, and also, in the case of the latter, from fluorine. Sodium is not, however, able to reduce all the metals of the earths from their chlorides, as was once erroneously supposed. Matthiessen has shown that what was supposed to be calcium—obtained by the reaction of sodium or of potassium upon chloride of calcium—was only a combination of potassium with silicium and aluminium, a result which experiments completely confirm. Still this remains: that, possessed of sodium, we are able to obtain, in quantity, two metals and a metalloid; that is to say, aluminium, magnesium, and sodium, which exist in various combinations in such abundance as to make up, with oxygen, the greater portion by far of the earth's crust. The first of these, aluminium, is the only one which has as yet been transferred from the laboratory of the chemist to the workshop of the artisan. Aluminium leads the van of those metals which, although the most plentiful of all in nature, are not procurable by processes simply metallurgical, in the antiquated sense of that word. Dr. Percy, however, defines metallurgy as "the art of extracting metals from their ores, and adapting them to various processes of manufacture." This definition does not exclude processes usually considered chemical. Yet it would seem convenient to regard that branch of metallurgy which has the extraction of aluminium from a prepared ore of aluminium for its type as "chemical metallurgy," a new art which calls Deville father.

* "The Engineers' Pocket-Remembrancer. An Epitome of Data, Rules, and Formulæ, applicable to Civil, Mechanical, Marine, Hydraulic, Lighthouse, Telegraphic, Railway, and Gas Engineering, Surveying, &c." By Francis Campin, C.E. London: Atchley and Co., 106, Great Russel-street. 1863.

† Specification of Edward Sonstadt. "Improvements in the Manufacture of the Metal Magnesium." Patent dated November 8, 1862. London: Great Seal Patent Office, 1863. "Du Magnésium:" par MM. H. Sainte-Claire Deville et H. Caron. *Annales de Chimie et de Physique.* Mars, 1863.

Excluding some three or four rare and little-used metals—as palladium, rhodium, iridium—there were, prior to the introduction of sodium and of aluminium, but twelve metals used for industrial purposes in either a pure metallic state or in alloy. These metals are gold, silver, iron, copper, tin, lead, mercury, zinc, antimony, nickel, bismuth, and platinum.* Of all these metals, the ores of iron alone can be considered abundant enough to be of geological importance. But far more abundant than iron itself are silicium, aluminium, calcium, and probably magnesium. Yet none of these, aluminium only excepted, are known to commerce. In the extraction and application of these metals, then, how magnificent is the field open before our generation!

Magnesium, although a less plentiful constituent of the earth's crust than calcium, enters into the constitution of a great variety of minerals. It is found occasionally combined with phosphoric and with boracic acids. But it is in combination with silicic acid that it is most universally diffused. Precious serpentine, and meerschaum, are hydrated silicates of magnesium. Venetian talc, white augite, amianthus, and the varieties of amphibole, are also examples of silicates of magnesium associated with more or less of foreign substances. Carbonate of magnesium constitutes a range of low hills in India. The rarer hydrate occurs in a few localities. But the most economically important mineral containing magnesium is Dolomite, which consists of carbonates of magnesium and of calcium, and usually overlies (with or without the intervention of sandstone conglomerate) the coal formation. In England the magnesian limestone formation extends, with little interval, from Tynemouth to Nottingham, a distance of 147 miles. At Sunderland the bed is fully 600 feet thick. It is this magnesian limestone which furnishes most, if not all, of the magnesia prepared in this country. Abroad, magnesia is economically obtained from the mother-liquors left after sea-water has been evaporated down for its salt. Probably these mother-liquors will ultimately turn out the best source of magnesium, since here the metal is associated with chlorine, and it is from the chloride that the metal is most readily procurable. Every ton of sea-water contains a fraction over two pounds avoirdupois of magnesium in combination with chlorine, and almost exactly half that quantity combined with sulphuric acid. A rough calculation shows that, if the surface of the ocean be taken at twice that of the land, and its average depth at three miles, then, the specific gravity of magnesium being 1·75, the ocean contains about 160,000 cubic miles of magnesium.

Davy, by means of his galvanic battery, proved the existence of magnesium, the basis of magnesia, of Epsom salts, &c., in 1808. Not till twenty years afterwards was it obtained by Bussy in sufficient quantity to allow of experiments upon its properties. The latest published process for obtaining magnesium is that given by Deville in the number of the *Annales de Chimie* for last March. The method is essentially the same as that devised by Bussy, but the details and the way of manipulating are described with admirable precision, and certain difficulties and disadvantages inherent to the process are pointed out for the first time in print.

To obtain magnesium by the method given in detail by Deville, the first necessary is anhydrous chloride of magnesium—that is, chloride of magnesium completely deprived of water. Now, when the hydrated chloride of magnesium is strongly heated, a portion of the water present is decomposed: the oxygen of the water displaces chlorine, forming magnesia, while the liberated chlorine seizes upon the hydrogen of the water, and escapes as hydrochloric acid gas. It is erroneously stated in some chemical text-books that this decomposition is complete, so that when hydrated chloride of magnesium is heated to redness nothing but magnesia remains, and a now happily unused method of estimating magnesium is based upon this supposed complete decomposition. M. Sonstadt has heated hydrated chloride of magnesium to redness, wetted it thoroughly with water, and again ignited it, seven times successively, and yet a considerable quantity of chlorine remained unexpelled. Nevertheless, it remains true that, when hydrated chloride of magnesium is heated to redness, even when as much as possible out of contact of air, the mass of mixed chloride and magnesia is infusible, and in a condition totally unfit for the extrication from it of magnesium. Three methods are known of obtaining anhydrous chloride of magnesium, only one of which will be mentioned here—that preferred, and justly preferred, by Deville. It consists simply in evaporating to dryness, and then heating to redness, in a covered crucible, solutions of the chlorides of magnesium and of ammonium, mixed in the proportion of their equivalents. Simple as this appears, it is not a very easy or a very certain process to conduct in porcelain crucibles; and whether the crucibles are of porcelain or of platinum, there is inevitably enormous waste, owing to the volatilization of a considerable portion of the chloride of magnesium in a state of chemical combination with the volatile chloride of ammonium. The amount of the loss thus sustained, according to his experience, averages six-sevenths of the entire quantity of chloride of magnesium with which the experiment may be begun. But even the chloride of magnesium that remains is not free from magnesia, which settles to the bottom of the fused mass; and it is hardly possible to completely expel all traces of the ammoniacal salt, by howsoever prolonged ignition. But ammonium contains nitrogen, which, in the after process for getting the metal, combines with the magnesium, giving it a yellow tint, and rendering it extremely oxidable.

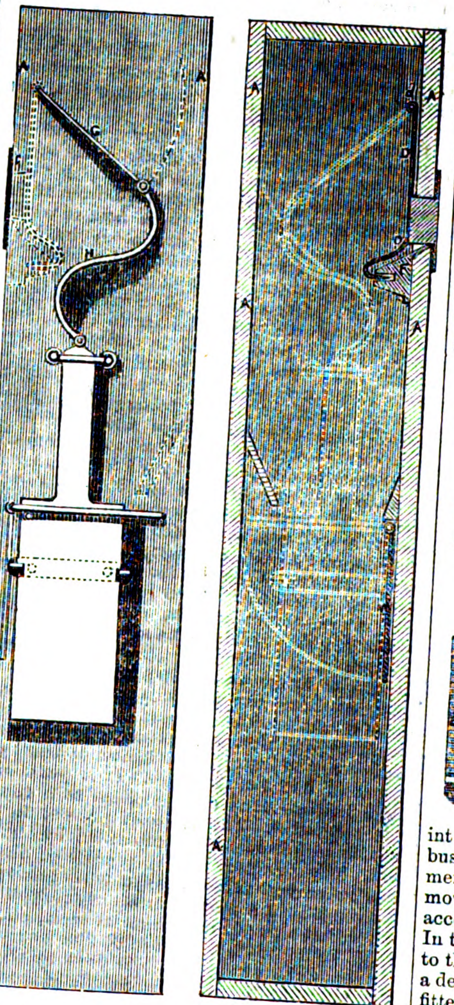
Recurring to Deville's process. Anhydrous chloride of magnesium being obtained—although not free from nitrogen—it is mixed with powdered fluor-spar, previously purified from silica and from phosphoric acid (with both of which fluor-spar is invariably associated) by long digestion in cold sulphuric acid, and subsequent washing with water and drying. To the mixture of 600 parts chloride of magnesium with 480 parts of the purified fluoride of calcium (such are the proportions) is added, in large pieces, 230 parts sodium; and the whole is thrown into a red-hot clay crucible, which is quickly covered. The heat being raised, the reaction is soon over. When the crucible is somewhat cooled the cover is removed, and the pasty mass is compressed by a broad iron rod, so as to push together into one lump the small globules of magnesium interspersed throughout. The magnesium thus formed contains carbon, silicium, and nitride of magnesium. From the two former impurities Deville separates magnesium by distillation of the impure metal in a tube of gas-retort carbon, enclosed air-tight within a glazed earthen tube. A strong heat is required, and throughout the whole process a current of hydrogen gas is passed through the tube containing the magnesium. A drawing is given of the distilling apparatus, from which it would appear that the carbon tube is about 6 decimetres in length, and has an internal diameter of 4 or 5 centimetres. It is possible to distil half-an-ounce of magnesium at a time in this apparatus. The nitrogen present in the impure magnesium is not separated by distillation. With respect to this process of distillation in carbon tubes it is only necessary to observe that the method is utterly inapplicable on any but a purely experimental scale, and few would be fortunate enough to be able to procure a carbon-tube even of the size used by Deville. The presence of silicium in the magnesium obtained in the clay crucible is due to the silica present in the clay. Magnesium has a remarkable affinity for silicium, and reduces it from all its compounds with great facility, so that it is impossible to obtain magnesium in a siliciureted crucible (an ordinary clay crucible is about half silica) without obtaining highly siliciureted magnesium. A platinum crucible cannot be safely used for the reaction, since a piece of magnesium heated in a platinum crucible will run a hole through it almost as quickly as a piece of lead will. Porcelain crucibles are objectionable on the same ground as clay crucibles, than which they are yet more silicious; besides which, they are very liable to break, and are restricted to a small size. The carbon described as existing in the crude magnesium is probably derived from naphtha adhering to the surface of the sodium used for reducing the magnesium. The only way to avoid the presence of carbon in magnesium is to use perfectly clean sodium. There is another impurity besides carbon, silicium, and nitrogen, contained in crude magnesium, to which the French chemist does not advert, but he states that the residuum left after distilling magnesium is of an unascertained, but exceedingly complex, nature, which evidences that he is aware of the presence of at least one unascertained impurity beyond the three specified. The nature of this fourth impurity will be treated of further on.

The new process for preparing magnesium, which it is supposed will be applicable on a manufacturing scale, is based upon the two following main facts: (1) That when a mixed solution of the chlorides of magnesium and of sodium is evaporated to dryness and then heated to redness, a fused mass remains, which, heated with sodium, gives magnesium; and (2) That magnesium does not sensibly act upon iron when air is excluded and the heat is not raised excessively high. Hence it follows that iron vessels may be used in which to effect the reaction of sodium upon the "material," or fused mass obtained as described. These are the two hinges upon which swings the gate, which, it is trusted, will open a new room in the house of Industry for the occupancy of man. The process being independent of the use of chloride of ammonium, saves the loss incurred when that salt is volatilized off chloride of magnesium; the enormous waste of the magnesium chloride which occurs in the old process is also prevented; nitrogen is not present in the "material" thus made; and the manipulation of the new process is so easy that it has been successfully conducted in my laboratory during my absence by an unskilled servant-lad. When clay crucibles are used for every operation; the size of the vessels can hardly be increased beyond certain narrow limits; and the magnesium obtained in clay vessels cannot be other than siliciureted. A good iron crucible, on the other hand, will last, with care, for more than a hundred operations, as my experience has proved; its size may be increased at will; and the magnesium (unlike aluminium, which may not be prepared in iron vessels), derives nothing from the iron. But there are two minor matters which require mention. The first of these is that the magnesia of commerce is unfit, owing to the presence of sulphates in it, for the production of magnesium; wherefore, if the mother-liquors of sea-water are not accessible, magnesia requires to be specially prepared, in view of the manufacture of magnesium from it. This special preparation simply consists in the thorough washing with pure water of freshly precipitated carbonate of magnesia, then drying by pressure, washing again, and so on, until the wash waters—properly acidulated—give no precipitate with chloride of barium. The other point relates to a new method of obtaining anhydrous chloride of magnesium, which consists in heating the hydrated chloride up to redness in a current of perfectly dry hydrochloric acid gas, which carries off the water associated with the chloride. The fused chloride of magnesium thus obtained may be used for the production of magnesium, or as a bath in which, when crude magnesium is fused, it becomes freed from sodium, with which it is usually alloyed in its crude condition. The magnesium obtained by the foregoing process is still impure, and therefore may be distilled with advantage. The description of M. Sonstadt's method of distilling magnesium (which is applicable on any scale); the details of the processes just cursorily described; and an account of the properties, chemical and mechanical, of magnesium, M. Sonstadt reserved for a second paper.

Reference was made above to a "fourth" impurity, always present in crude magnesium, but which, it was hinted, had not yet been described. This M. Sonstadt takes to be a new metal, not hitherto recognised. His researches into this matter began about eighteen months ago; but it was only a few weeks back that, after numberless failures, he hit upon a method of procuring a salt of the metal in what there is reason to believe is a state of purity. The quantity obtained was very small, little over a grain. Nevertheless, partly from previous experiments upon the impure element, partly from such as could be made on the little that was obtained in purity, the following partial description of its reactions and properties may be relied upon. [For convenience of naming, and provisionally, M. Sonstadt calls this metal X.] The most remarkable feature about the salts of X is their wonderfully close chemical resemblance to those of iron, and to this circumstance must be attributed the late discovery of the metal, which must have appeared as iron in many hundreds of analyses, for there can hardly be a laboratory in this country in which an oxide or salt of X, in a state approaching purity, has not been repeatedly obtained, and set down as iron. As with iron, the salts of X give a blood-red colour with sulphocyanide of potassium. As with iron, its acid peroxide and perchloride solutions give a blue precipitate with yellow prussiate of potash, and also, after treatment with a reducing agent, as hyposulphite of soda, with red prussiate. But, unlike true Prussian blues, the blues given by X are unchanged, if pure, by excess of ammonia, no matter how large that excess, or for how long digested with the precipitate. If the solution of X be slightly contaminated with iron, the blue precipitate changes to purple on addition of ammonia, and, if much iron be present, gradually passes to the usual iron-brownish-red. The time which is required to effect this change in the blue from impure solutions of X, is an excellent indication of the degree in which it is contaminated with iron. If Pattinson's calcined magnesia be dissolved in excess of pure hydrochloric acid, and the solution, concentrated by boiling, be tested with solution of yellow prussiate, the blue colour formed will slowly change to purple, and still more slowly to brown, on addition of excess of ammonia. It is almost unnecessary to remark that there should be enough chloride of ammonium present in the solution tested to hold up the magnesium on addition of the excess of ammonia. In this experiment, an impure solution of X, containing iron, is tested; yet the reaction described is very distinct from that of iron. To obtain a pure solution of X, about one part amorphous phosphorus should be intimately mixed with eight parts calcined magnesia of commerce, and the mixture ignited in a covered porcelain crucible, until phosphorous fumes cease to be evolved. The whitey-grey mass that remains is digested in hydrochloric acid, the solution is poured off, and more acid added to, and boiled upon, the residue. The solution is again poured off, and the residue is boiled for several hours in fresh portions of acid. The well-washed residue, which is nearly black, is then ignited with hydrate of sodium, the mixture is dissolved in water, and the deposit washed with repeated portions of water by decantation. The process of washing is tedious, as the matter (which is of a yellowish colour) is very slow in subsiding. The acid solution of the well-washed deposit gives the pure reactions of X. It is evident that this process excludes the possibility of the presence of iron with the oxide of X. The theory of the process is, clearly, that the phosphorus reduces the mixed oxides of iron and of X to the metallic state, or to the condition of a lower oxide; and that in this condition, X, or its low oxide, whichever the black powder may be, is unattackable by hydrochloric acid, whereas the iron is taken up, and so separated. The black powder, when thrown into the fused hydrate of sodium, causes effervescence. It seizes oxygen from the water of the soda, and liberates hydrogen. The oxide of X thus formed is that which corresponds with the sesquioxide of iron, as is proved by its acid solution giving the blue (unchangeable by excess of ammonia), not with red, but with yellow, prussiate of potash. Its precipitate with an alkali, when ignited before the blow-pipe on charcoal, requires much more intense heat for its reduction than ferric oxide requires, and the dark spongy mass at last obtained is not in the slightest degree attracted by the magnet. He has not yet found any reagent capable of directly separating iron from X, when both are together in solution, nor any solvents discriminative of their respective precipitates. The consideration of the important bearings which X has upon the theory and practice of the methods of obtaining magnesium, must, like the other deferred matters, be postponed to a second paper.

SIMPSON'S LETTER-BOX.

In order to prevent the withdrawal of letters from boxes or other receptacles in the doors of dwelling-houses and offices, the invention, which we illustrate in the accompanying engravings, has been patented by Mr. W. Simpson, of Liverpool.



A is the casing forming the letter-box, and enclosing a lever and other appliances; C, a fixed plate surrounding the receiving opening, which is similar to that of most ordinary letter-boxes; *d* is a joint formed on the interior front of the box, to which is attached D, a swinging cover, the front of which is formed with a block piece, which takes into and closes the opening through which the letters are introduced into the box, and the lower edge of which is bent, and forms a cutter in conjunction with F, a metal block fixed across the inside of the box immediately below the receiving opening, and which block is constructed with a longitudinal horizontal slot forming two cutting edges between which the horizontal lower edge of the flap works and acts as a pair of shears for cutting twine, wire, or other like material which may be used for attempting to extract the letters or other articles deposited in the box; G, is a lever arm attached to the axle of and actuated by the flap or swinging cover, to the outer end of which is jointed a curved connecting link rod jointed to the top of the shank of a weight working within guides; a stud pin on the vertical sliding plate acts against the under side, and elevates the cut-off plate M to a horizontal position. The lever divides the box into an upper and lower chamber, when the lower edge of the port covers is pressed sufficiently backwards by the hand or otherwise to be clear of the cutter block. N is a guard fixed across the back of the box. The hinged plates are furnished with a sharp serrated cutter edge. The operation is as follows:— On pushing back the swinging cover D by pressing on the block, the lower edge of the flap D will be withdrawn from between the jaws of the block, and the lever G connected to the axle thereof will be elevated, end carry with it the curved connecting rod H and the weight plate, the stud piece acting on the under side of the lever will be brought up to a vertical position before the lower edge of the flap D has left the jaws of the block F, and the swinging guard M will be brought into a horizontal position, dividing the box into an upper and lower chamber, when a letter or other article may be pushed through the opening E, when it will fall upon the top of the tilt-plate M, where it will remain until the pressure on the block is removed, and the lower edge of the flap D again enters the jaws of the block.

SHANKS' LAWN MOWING MACHINE.

Mr. Shanks, of Arbroath, has recently patented further improvements in machines for cutting grass. The improvements consist—1, In dispensing with the ordinary cutter bracket with the screw for raising it up and down, and in substitution thereof an eccentric bush, fitted into the frame of the machine. This eccentric bush is provided with a slotted flange, and by merely turning it round the cutter or actual mower is raised or lowered as may be desired, according to the direction of the turning. 2, In the placing or attaching a flap or pendent end to the grass box of the machine when fitted with a delivery apparatus. This arrangement is so fitted that when the travelling end is at one end of the box the flap at the other end is down, and this part opens when the travelling end begins to move.

FIG. 1.

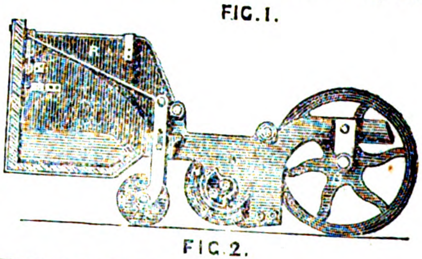


FIG. 2.

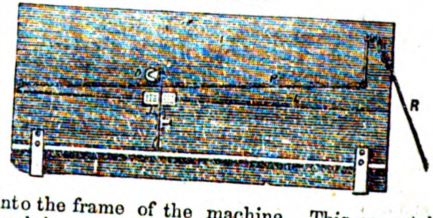

The framing A of the machine, shown at fig. 1, is of the usual construction; the after part is supported on the duplex rollers B, whilst the forward part of the frame is carried on the rollers C, which may be adjusted so as to regulate the height of the machine from the ground. At the central part the framing extends downwards, partially covering the open cylindrical frame to which the helical cutters are fixed. To the outside of the framing at this part is fitted a quadrant on each side of the machine. These have formed in them a segmental slot, as shown. Each quadrant or bush is retained in the desired position by means of a screw and pinching nut which hold it firmly in position. The bushes are carried on the cutter shaft. The object of this arrangement is to afford a ready and efficient means of adjusting the height of the cutter from the sole plate. This is done by loosening the nut and turning the bush round to the desired extent, so as to raise or lower the bearings of the spindle.

Another improvement in connection with these machines consists in an arrangement for instantaneously discharging the contents of the grass box without requiring the machine to be stopped or otherwise interfering with the progress of the work. The grass box or receiver I, into which the grass is thrown by the action of the rapidly revolving cutter H, is fitted with a moveable partition or travelling end piece J, which serves, when moved from end to end of the grass box, to deliver the cut grass in a body out at the side of the machine. This end piece J is fitted on the outer edge with a grooved pulley, which runs to and fro on the horizontal bar or rail L, fixed to the back of the grass box. The end piece is also fitted with a pulley at the lower part where it traverses over the shelving part of the box I, so as to cause it to move easily to and fro. A socket is bolted to the end piece, and to this socket is jointed the front end of a hand lever, which extends upwards and in a backward direction so as to be within convenient reach of the person guiding the machine. When the end piece is caused to move from left to right, or from one end of the box to the other, for the purpose of discharging the cut grass, it also operates a flap door which is arranged at the opposite end of the grass box. At the upper part of the end piece is fitted a pulley O, which traverses to and fro on the angular bar P. This bar or rod is centered at one end on a pin projecting out from the face of the box I, and at the other it is jointed to the bell crank lever. The horizontal arm of the lever is connected to the swinging flap door R, which is hung. When the operator desires to discharge the cut grass from the box I, a simple movement of the hand lever, from right to left, will cause the end piece to traverse in the opposite direction. As the end piece moves along, the pulley O depresses the rod P, which draws down the crank lever and raises the flap door R, so that the grass is free of any obstruction. The operator instantly releases the hand lever, when the weight of the flap R causes the pulley O to descend the bar P rapidly; and thus restores the end piece to its normal position. In this way the person guiding the machine can by an exceedingly simple movement discharge the grass from the box I from time to time as required.

CAPTAIN NORTON'S IMPROVED RIFLE SHELL.

Captain J. Norton, late of Her Majesty's 34th Regiment, has sent us a rifle shell, having a parchment sabot fitting tightly thereon, as clearly shown in the annexed sketch. The parchment is put on wet, in two or three layers, and then pressed through an iron tube; when the parchment is dry, it becomes as close-grained and hard as ivory. The sabot is divided into five divisions, like fingers, which relax their grip and fall to the rear on leaving the muzzle of the rifle. The shell within the sabot is rifled, and is adapted to the three-deep-grooved rifle. We believe the above shell is intended to compete against the Armstrong lead-jacketed shot or shell according to the challenge issued by Captain Norton.

SPRUYT'S IMPROVEMENTS IN RAILWAY RAILS.

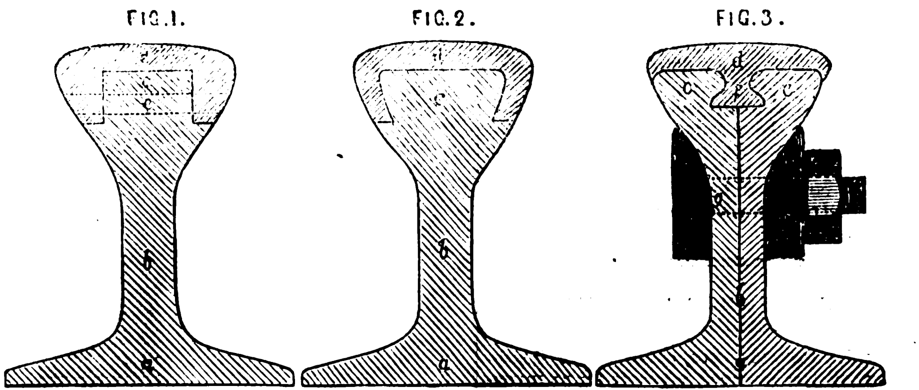

FIG. 1. FIG. 2. FIG. 3.

SPRUYT'S IMPROVEMENTS IN RAILWAY RAILS.

The accompanying engravings illustrate three sectional views of railway rails of an invention just patented by Mr. C. W. Spruyt, of New Broad-street. The invention consists in forming rails in two parts—the foot, the web, and a shoe in one piece; and the top in another piece. The top is shrunk, bolted, or otherwise attached to the shoe, and when worn it can be removed, and another top may be fixed on the same shoe.

The invention also consists in inserting between the shoe and the top a layer of lead, hardened rubber, or other material softer than iron.

Fig. 1 shows in transverse section one method of forming rails. The rail is formed of two parts—the foot *a*, web *b*, and a shoe *c* being in one piece; and the top *d* in another piece. The top *d* is placed upon the shoe *c*, and secured thereto by pins *e*, placed at suitable distances apart.

Fig. 2 shows a modification of the form of rail represented in fig. 1, in which the upper part of the shoe *c* is bulged out or enlarged, so that the top *d*, which is of corresponding shape, is held without the aid of pins. The top *d* may in this case be drawn longitudinally on to the shoe *c*, while hot, so that the shrinking consequent upon the cooling may cause it to grasp the shoe more tightly. The top *d* is formed of steel, which would be annealed by being brought into contact with the red-hot iron.

In fig. 3 the foot *a*, web *b*, and shoe *c* are divided longitudinally, and the top *d* is formed with a tongue *f*, which is securely held between the halves of the shoe *c* upon the screwing up of bolts *g* and nuts *h*; *i* is a washer, held between the web *b* and nut *h*. If desired, the tongue *f* may be carried down between the halves of the web *b* far enough for the bolts *g* to pass through it. A layer of lead, india rubber, or other material softer than iron may be inserted between the shoe *c* and top *d*, and if desired, the upper surfaces of the shoe may be made slightly concave, and a thin strip or sheet of steel placed thereon, so as so act as a spring, and thereby compensate for any want of straightness in the rails.

IRRIGATION WORKS IN INDIA.

We see with pleasure that many projects for the extension of railway and canal communication are likely to be carried out in India. The increased development of her resources cannot fail to prove advantageous both to herself and England.

The Calcutta correspondent of the *Times* says:—Sir Arthur Cotton, the well-known Madras engineer, who after a short visit to India returns to England by steamer, delivered a lecture to the Bengal Chamber of Commerce on works of irrigation in India. He was a little bitter, and not always unjust, in his condemnation of the acts of the East India Company, and of the administration of the present Public Works Department, and he quite bore out the truth of the charge which, he said, Sir Charles Wood applied to him, of being a sanguine man. Still, Sir Arthur Cotton has acheived too much for the people and the revenue by his hydraulic works in his own Presidency; and his accusation that the Government make great works, like the Ganges Canal, which will not pay because a little more money is grudged to complete them, is too truly borne out by the late Lord Canning's minute, not to give weight to his words at the present time of transition from State management to private enterprise. He has been engaged to report on projects to be taken up by the East Indian Irrigation Company in Northern India without a guarantee on its capital. That company is at present at work in Orissa, but Sir Arthur Cotton contemplates a series of hydraulic works between Allahabad and Calcutta, which are the natural limits to the Ganges stream of irrigation and navigation. Major Dickens drew up a scheme for the irrigation from the Soane of Behar which, in Mussulmen days, was the garden of India. As the scheme involved more than a million sterling of expenditure, Sir C. Wood was asked by the Indian Government to recommend it to private capitalists. Sir Arthur Cotton has partially taken it up. By throwing a dam across the Soane, a little below the Grand Trunk-road, he says a line of canal can be led on a dead level for 170 miles to Allahabad. He would, by other parts of "the Behar project," not only irrigate 2,250,000 acres, but send an ample supply of water to Calcutta, where it is so much wanted, raising it to a pressure of 100 ft., so as to supply the highest houses. Then there is the "Oude project" for irrigating the whole area from Rohilcund to the Ganges, with the North-western districts of Bengal Proper. By leading water from Ronagunge, Calcutta would receive the produce of these rich and distant provinces. The contract for the Behar project between Government and the company has been approved, with modifications, by the Secretary of State, and is now with Lord Elgin. Thus definite projects for extensive lines of railway and canals of irrigation and navigation are about to be carried out, so as to make the most distant parts of long-neglected Oude and Rohilcund accessible. If you ask whether these projects will pay, I say all depends on the engineers employed and the supervision of expenditure combined. The East Indian Railway had clever engineers, but it was nobody's interest to check peculation, and so the line cost £16,000 a mile. Even where private contractors constructed a line, as in the case of the Eastern Bengal Railway, the cost was great, though nothing like this, both because of the scarcity of labour and the fraud of the labourers and their suppliers. The projects will undoubtedly pay if these two requisites are secured in the agents—skill and honesty. There is some truth in what Sir A. Cotton says. We spend nearly ten millions a year on public works, one-half of which is out of current revenue. Of this, one-half, again, is devoted to new and reproductive works, yet we do not keep a separate account of these, but lump up the proceeds with land revenue. If the accounts of any one work—say the Godavery irrigation canals—were kept distinct, then enormous profit would be seen; they would be completed, and their patent success would lead to the extension of similar works. He would put all our public works under a Board of Commissioners, but he fails to show that a mere change of name, or even organization, without a change of system, would effect any good. The Madras Irrigation Company, even with, and, perhaps, because of its guaranteed capital, has as yet done little. But this much is certain, that now the great trunk lines of railway, primarily necessary for political reasons, are approaching completion, works of combined irrigation and navigation should receive as much encouragement as branch railways.

EASTON AND AMOS' WOOD SAWING MACHINERY.

Messrs. Easton and Amos, of the Grove, Southwark, have just obtained a patent for an invention of improved machinery for sawing wood.

The object of this invention is to render sawing machines more efficient in their operation than heretofore. To this end, in order to secure the log from rising with the drag of the saw on its bed while being cut, the patentees keep it down by means of pressing rollers or bowles carried by vertical water cylinders, in which stationary pistons are inserted, their rods being pendent from a transverse beam of the saw-frame. The upper and lower ends of each cylinder are brought into communication by an outside pipe, which allows of the water which fills the cylinders to pass from one to the other side of the fixed pistons. The water forms an elastic packing between the piston and the lower ends of the cylinder, and serves to retain the bowles of the cylinders in contact with the timber when once lowered in contact therewith.

As this machine would be required to operate upon balks or logs of varying thickness, the cylinders C are fitted with a vertical rack, as shown in the engravings, in gear with pinions for raising and lowering the cylinders; by this means the position of the cylinders may be adjusted to suit varying sizes of timber. It will, of course, be understood that while the cylinders are thus being raised or lowered the water confined within them will slowly escape from one side of the pistons to the other, so as to allow of the vertical movement of the cylinders.

It will be seen on reference to fig. 1 that the apparatus consists of a fixed piston A, and moveable cylinder C. The piston A and its rod should by preference be of wrought iron, and is secured to the cross frame B of the machine so as to be firm and rigid. Upon this piston and rod works a hydraulic cylinder C, of such length of stroke as will admit of the largest size balk intended to be cut by the machine being placed beneath it. A press roll D is connected by a cross head E to the lower extremity of the cylinder C, and bears upon the balk of timber. The cross head E works in suitable guides so as to keep the cylinder C in its traverse truly vertical. A pipe F, provided with a stop-cock, opens a communication between the upper and lower sides of the piston; and in actual work the cylinder C is filled completely with water, the cock being closed very nearly, in order to give the requisite resistance. It will now be seen that should the saws at the up stroke "lay hold" of the timber, as they frequently do, so as to lift the balk from the machine bed, the effect of this sudden lift will be to raise the cylinder C slightly, and drive the water through the pipe F to the upper side of the piston; but as a great resistance will be produced by the water endeavouring to pass through the nearly closed cock, this resistance will effectually prevent the further rising of the cylinder and the jumping up of the timber. On the other hand, the cylinder must necessarily rise and fall to suit the inequalities of the timber, but such rising will be very gradual and moderate compared with the sudden lift produced by the "laying hold" of the saws.

In order to ensure the rapid falling of the cylinders so as to be always in contact with the timber, a small valve in the piston opening downwards is provided, so as to give free passage for the water between the top and bottom of the piston when the cylinder is falling. The valve will, however, prevent the passage of the water in the contrary direction.

It frequently becomes necessary to move or traverse the bed or table of the machine upon which the timber rests quickly to and fro—as in the case of returning for a fresh cut, for instance—and at such times it is desirable to have the saws themselves stationary for adjustment; this is ordinarily accomplished by providing a separate driving motion from the main shaft in cases where saw-frames are driven from a detached steam engine or other prime mover; but it is obvious that such an arrangement cannot be obtained in the case of a machine where the saw-frame and engine are combined. In such a case, or in such other cases where a separate driving motion from the main shaft cannot easily be had, the patentees employ a separate small engine J, fig. 2, provided with any ordinary reversing movement arranged so as to cause the bed to run in either direction. A lever K is employed to turn the starting cock of this engine in connection with the working pawls L of the feed motion, by means of the coupling rod and lever M, so that the engine cannot be started without throwing the pawls L out of gear, and thus preventing the possibility of accident to the feed motion. This coupling rod movement may also be connected with the starting lever of the traversing gear of the ordinary saw frames.

EASTON AND AMOS' WOOD SAWING MACHINERY.

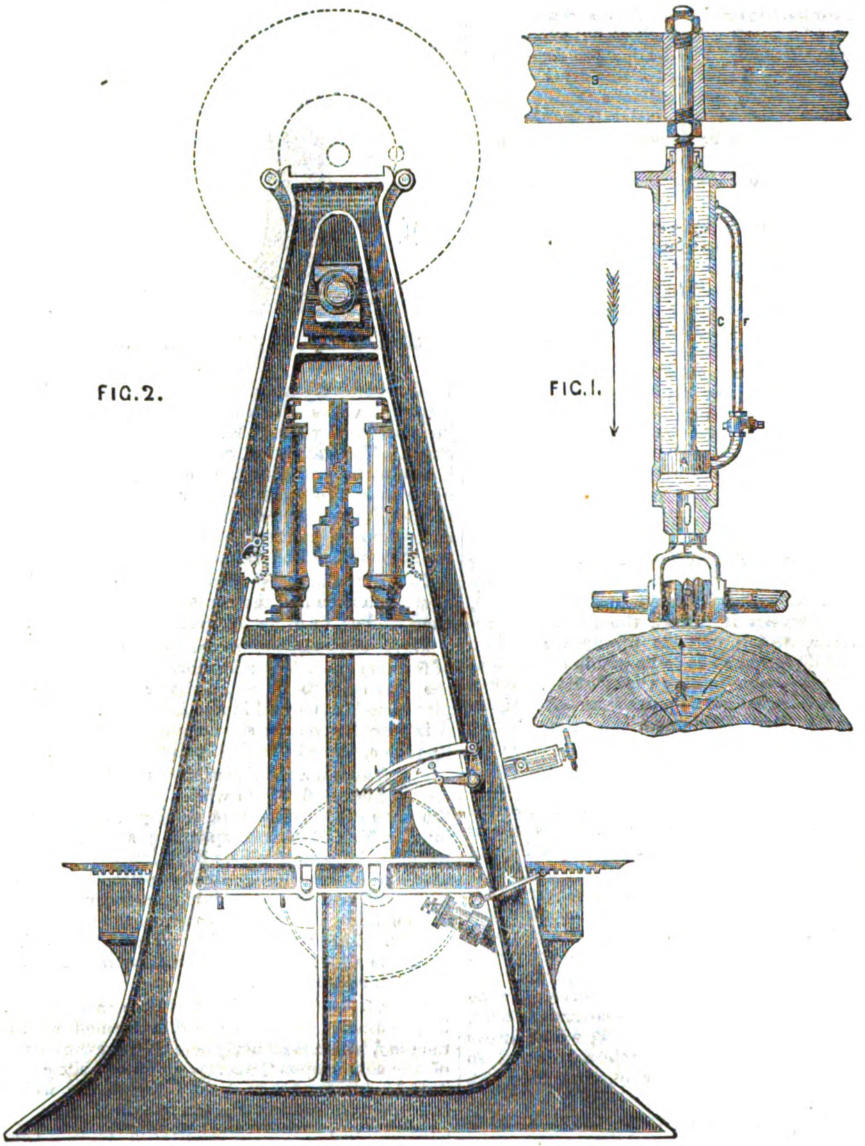

FIG. 2.

FIG. 1.

FAULDING'S IMPROVEMENTS IN LOCOMOTIVE ENGINES.

Mr. J. Faulding, of Euston-road, has patented some improvements in locomotive engines, which he describes as follows:—

The object of this invention is to obviate the inertia and momentum of the working parts of a locomotive engine, and my improvements consist in placing duplex oscillating cylinders C, C, on a horizontal line with the centres of the two driving axles I, I, in such a manner that the cylinders, with the whole working gear of the engines, are carried by an independent frame K, K, supported on journals L, L, on the two driving axles, so that the relative connections of the engines with the driving axles shall not be influenced in any degree by the play of the springs which carry the ordinary framing, boiler, &c. The piston rods are coupled direct to the crank pins F, F, which are fixed on the bosses of the driving wheels G, G. It will be obvious, then, that when the pistons D, D, are simultaneously driven outward, and by the return stroke are brought simultaneously towards the centre, the half of the power will be given to one driving wheel, and an equal power to the second driving wheel. The inertia and momentum of one piston will be perfectly balanced by that of the other, entirely doing away with the usual zig-zag motion of the locomotive caused by the action of the single piston, with its

FAULDING'S IMPROVEMENTS IN LOCOMOTIVE ENGINES.

FIG. I.

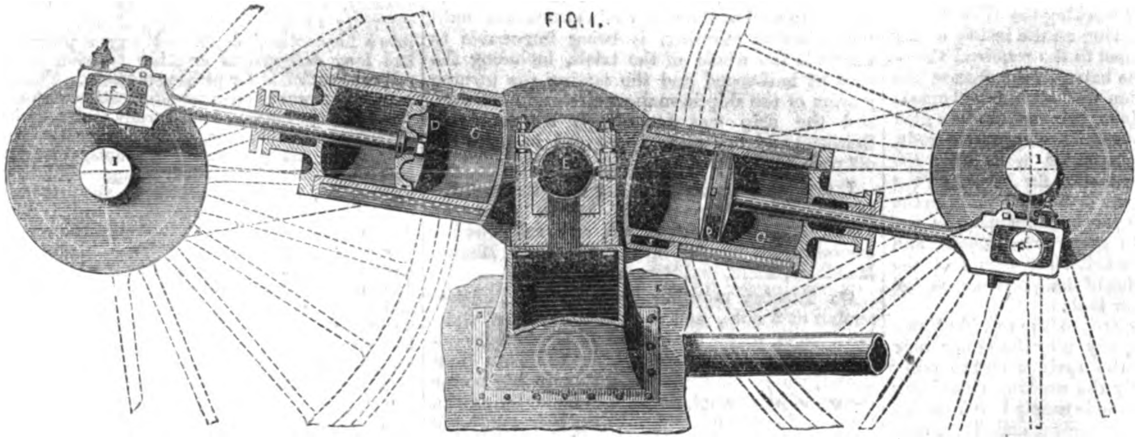

FIG. 2.

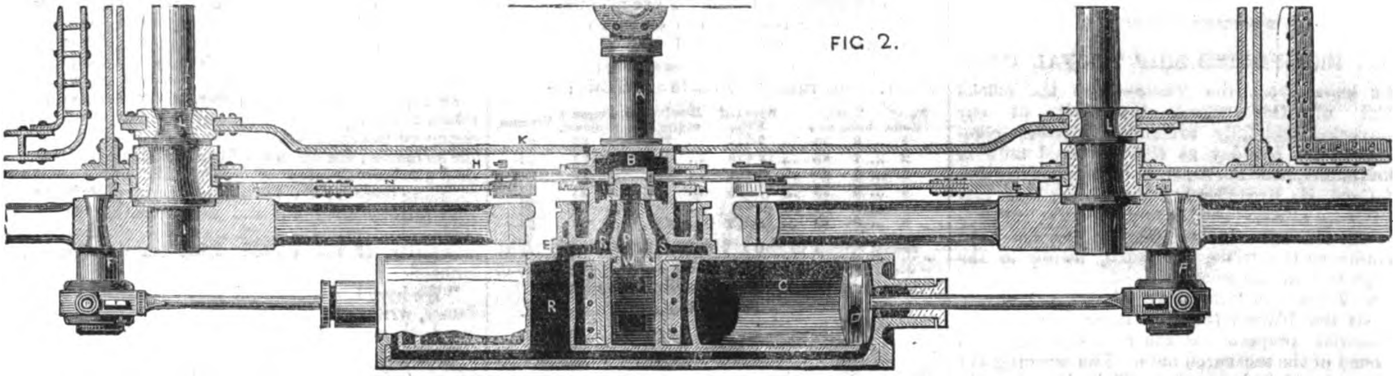
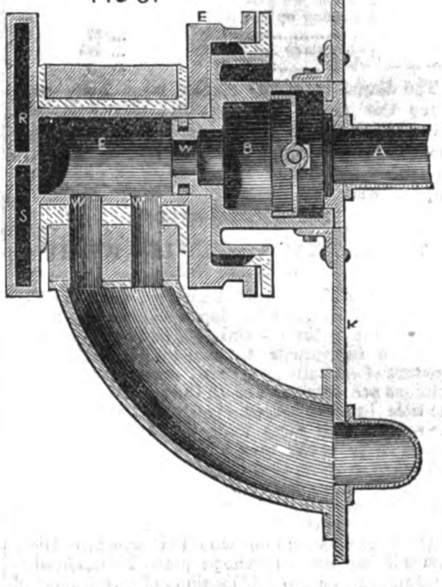


connections acting alternately on the cranks placed at right angles to each other, forcing first one driving wheel and then the other, and that the arrangement of the working gear, with the use of the single valve to each duplex cylinder, gives great compactness, and finally, that by so balancing the reciprocating mechanism of the engine, I obtain much greater steadiness at high speeds. In the first place, I take the steam direct from the dome on the top of the boiler by on oval steam pipe A, which I pass round the boiler to the underneath side, where it joins a pipe, the end of which is connected to the horizontal steam pipe A^1 to each pair of cylinders by a faucit joint and stuffing-box, the horizontal steam pipe being bolted to the flange of the slide valve casing fixed to the inner frame K, K. Thist arrangement is necessary, in order to allow for the up-and-down play from the action of the springs. I use two frames (as before stated) H and K, the inner frame being entirely independent of the outer frame, and to this inner frame I bolt the whole of the working machinery, including the cylinders. I bend the inside frame, where required, in order to clear the axle-boxes of the outside frame; on this inside frame I bolt the inside axle-boxes L, L, and thus obtain a rigid and independent foundation for the engine. I use two duplex cylinders C, C, placed on the outside of the driving wheels, and I join them at the bottom by a vertical flat steam chamber E, placed on the inner and outer side, and a circular cast-iron chamber placed transversely from these outside vertical chambers and joining the two, having openings W on the bottom side, which form a portion of the eduction passage; the circular chamber forms the trunnion on which the cylinders oscillate, and which works in the brasses of the plummer block, bolted to a curved wrought-iron bracket, which bracket is again bolted to the inside frame K, K, and, being made hollow, it forms the eduction passage for the steam to the exhaust pipe, in communication with the bracket on the inside frame K at one end, and the other with the blast pipe in the smoke box. It is clearly shown, then, that the cylinders being allowed to oscillate in their bearings fixed to the inside frame, are not acted on by any movement of the boiler, being independent of the action of the springs placed on the outside frame H, and on which the boiler rests. On the outside of the boss of each wheel I fix a crank pin, and I attach the piston rods to these pins by the ordinary straps and cotter, and the driving axles I, I, being straight, pass under and close to the barrel of the boiler. I cast a separate valve chest B, containing the steam and exhaust ports and passages, which I bolt to the inside frame K, and which, in fact, is a fixture, particularly that portion containing the ports on which the slide valve works, and which portion is square, or nearly so; but that portion which contains the steam and exhaust passages is circular, and projects into the trunnion of the cylinder. The joints of the connections between the two are made steam-tight; thus the outer one by the stuffing-box and gland, and the inside projection in the trunnion by a metallic packing consisting of a ring and spring with a bottom plate bolted on, as shown, similar to the packing of an ordinary piston.

FIG 3.



It will thus be clearly seen that, as the cylinders oscillate, the valve chest and ports remain stationary, allowing the lower portion of the steam and exhaust passages to move round them with a semicircular motion. I make one slide valve with the ordinary steam and exhaust ports answer the purpose for both cylinders, because it will be seen by the drawings that both pistons perform a similar duty, viz., front stroke and back stroke at the same moment; thus, when the pistons D, D, are at the bottom of their stroke and working simultaneously, the steam, after passing the valve, proceeds through the under passage of the front cylinder S, and acts on the bottoms of both pistons simultaneously. This steam, after having performed its duty, returns by the same passage to the exhaust port, and proceeds by the exhaust passages in the cylinder trunnion down the inside of the bracket to the exhaust pipe. The return stroke is made by the steam passing along the passage R over the back cylinder to the outside passage in the steam casing, which, it will be seen, communicates with both top steam ports, and the steam, acting simultaneously on the tops of both pistons, causes them to converge, and thus effect the return stroke, the waste steam passing along the same passage in return to the exhaust port. It will, therefore, be clearly seen that as the piston rods are connected to the pins on the bosses of the driving wheels, and as the pistons make a simultaneously outward and inward stroke, and the cylinders being allowed to oscillate on their trunnions, the two driving wheels revolve together either in a forward or backward direction, as required. The pins of the right-hand driving wheels are placed at right angles to the pins of the left-hand driving wheels; therefore, when the pistons are at the top stroke in the right-hand cylinder, the left-hand pistons are at half-stroke.

The arrangement for working the slide valves is this:—I bolt an iron ring on the inside of the boss of the driving wheel to the required throw of the valve, and place between the frames the ordinary slot link motion worked by a bell crank, which, acting on the links, brings them into gear on the slide valve rods and the eccentric rods, connected to the straps which work over the eccentric rings, the connection for reversing the engine being made by the ordinary handle on the driving platform. By this arrangement of the slide valve gear, I gain great compactness, and the whole of the space below the barrel of the boiler (with the exception of that portion occupied by the axles) for a water tank.

The boiler being bolted to the outside frame resting on the springs, any play the boiler may have is received on the springs on the outer frame, and consequently the working machinery placed on the inside frame is totally free from this action, being totally independent and rigid, with free action to perform its work.

THE IRON-PLATED SHIP "ROYAL OAK."

WE learn from the *Times*—That the official trial of this vessel, the first of our converted and fully armoured frigates, commenced on Monday at the measured mile in Stokes Bay, near Portsmouth, under the direction of Capt. H. Broadhead, commanding Her Majesty's ship "Asia" and the steam reserve at Portsmouth. Two previous attempts had been made to commence the trials, but failed, owing to the rough state of the weather.

At 9 a.m. the "Royal Oak" steamed out towards the Warner Light, to clear her fires and otherwise prepare for the race over the trial ground of the measured mile. The morning was fine with a light breeze from W. by N., just sufficient to furnish a good draught to the fires, but not prejudical to the ship's way when going against it. On reaching the lightship her course was altered, the ship's head being laid for Stokes Bay, where the trials of speed with full boiler power were at once entered upon, and completed with the following results.

No. of Run.	Revolution of Engines.	Time m.	Time sec.	Speed of Ship in Knots.	Pressure of Steam.	Vacuum.
1	59	4	55	12·203	22lb.	22½in.
2	61½	4	40	12·500		
3	61	4	40	12·857		
4	61	5	2	11·920		
5	61½	4	30	13·333		
6	61	5	9	11·650		

First mean speed in knots, 12·351, 12·678, 12·388,1 2·626, 12·941; second mean speed in knots 12·514, 14·533, 12·507, 12·558. Mean speed of the ship, 12·528 knots. Draught of water; 23 ft. 1 in. forward, and 25 ft. 7 in. aft; displacement of hull, 7,400 tons.

In making the first run at the mile the temperatures were recorded as follow:—On deck, 68 deg.; in engine-room, 73 deg., 73 deg., and 76 deg.; in the forward stokehole—fore part 84 deg., middle 109 deg., and after part 113 deg.; in after stokehole—fore part 103 deg., middle 105 deg., and after part 103 deg.

In the sixth mile run they were as follow:—On deck, 69 deg.; in engine-room, 72 deg., 72 deg., and 75 deg.; in forward stokehole—fore part 91 deg., middle 120 deg., and after part 112 deg.; in after stokehole—fore part 102 deg., middle 104 deg., and after part 103 deg.

The speed attained by the "Royal Oak" must be considered in the highest degree satisfactory, in all the sense of the words, if it is considered that the ship's "official" estimated speed was set down as 11½ knots, and that she has actually exceeded that rate by over one knot per hour.

The steering of the ship is managed by a simple reversion to the old gun-room tiller, *i.e.*, a long straight tiller projecting from the rudder-head into the after cabin, in a line with the keel; and the manner in which the ship answered her helm on Monday satisfied all on board that the resumption of the old description of tiller has given back to our ships some considerable portion at least of their old power of answering the helm, even before the introduction of the screw.

At the close of the full-power runs it was resolved to anchor the ship again at Spithead until the following morning, it being impossible to conclude the whole of the trials, including the runs at half-speed and the testing the turning powers of the ship in making circles, in one day, and the ship was accordingly steamed into Spithead and her anchor dropped in nearly its old position.

It is almost needless to say that the working of the ship's engines and boilers gave the greatest possible satisfaction, and reflected the customary credit upon the manufacturers, Messrs. Mandslay, Field, and Sons, of Lambeth.

On Tuesday morning the ship weighed her anchor at 8 a.m., and soon afterwards left Spithead again, under the charge of Captain Broadhead, for clear waters outside the Nab light vessel, where she could be tested in her power of turning and completing circles under full steam. On reaching the desired position, however, a hot bearing was discovered, and the full-speed circles had to be abandoned, and the programme of the ship's trials for the day cut down to six runs, with two boilers (one-third the ship's boiler power), and two circles afterwards with the same power. The runs were made as follows:—

No. of Runs.	Time. min.	Time. sec.	Speed of Ship.	Revolutions of Engines.	Pressure of Steam.	Vacuum.
1	8	19	7·214	35½	22	24
2	7	43	7·775	40½	22	23
3	6	49	8·801	37½	19	24½
4	8	26	7·114	38½	22	23
5	6	46	8·867	39	22	24
6	8	43	6·833	38	22	24

Mean speed of the six runs, 7·979 knots. The circles were made under the same conditions of power, and yielded the following results:—

	Circle to Starboard.	Circle to Port.
Time occupied in getting up the helm	27sec.	30sec.
Angle of rudder	26deg.	23½deg.
Turns of wheel	3½	3½
Time occupied in making half-circle	3min. 42sec.	3min. 43sec.
Ditto, full circle	7min. 27sec.	7min. 50sec.
Revolutions of engines previous to putting up the helm	37	37
Revolutions afterwards	35	34½
Men at the wheel	7	8

The diameter of the circles were little over twice the ship's length. The ship answered every touch of her helm as quickly and sensitively as a cutter, and her powers in this respect form a wonderful contrast to any other of our screw ships of war.

TESTIMONIAL TO WILLIAM HENRY JAMES, C.E.

THE *Mining Journal*, of Saturday, in a leading article, of which the following is an abstract, brings under public notice the claims of two comparatively unknown individuals to be considered—the originators of our railway system. So many conflicting opinions are expressed as to the relative claims of the title by different engineers, that we approach the subject with some little hesitation, preferring simply to place the question in its present aspect before our readers, that they may judge for themselves. Still, we believe we are correct in stating that the James's have fully as great a claim on public gratitude as George Stephenson; and the eminence of the individuals who have attached their names in furtherance of the proposed Testimonial to the James's, is a proof little short of convincing of the accuracy of the statements contained in our contemporary.

"There is a little work, entitled 'The Two James's and the two Stephensons.' As a matter of duty, the columns of this Journal were opened, many months since, to the discussion of its details. Upon the principle of justice between man and man, we laid the whole state of William James's case plainly before the public. That William James was 'the first great agitator and originator of the system of passenger transist on railways,' is made as clear as noon-day by the evidence adduced; and that George Stephenson was indebted to him for that inspiration which sent his, at that time, untutored intelligence hovering over the project organized by James, and upon which the evil destinies of the latter permitted it to swoop and to surge with rapacious appropriation, is equally apparent.

"The primary object of William James in making a tour of inspection through several parts of the country, where the tram-engines were used, was avowedly to find one 'capable of being converted into a locomotive,' fitted to the great purposes he had long designed of creating traction speed on railways sufficient for passenger traffic. This talisman, which was to open communication with all the wealth of the empire, he naturally took occasion to [illegible] with Stephenson, whose constructive genius a man of his penetration promptly discovered, and as readily, in warmth of appreciation, paid homage to, its tribute confidence the first impulse of a high cast, ingenuous mind, of which William James was, it appears, indubitably the possessor. The result was exactly as any foreseeing man might have indicated. In the Killingworth conference James lost his native secret of fame and fortune, and George Stephenson found it. Well; and more, he used it as a shrewd and clever man would, but he seems to have lost, in his upward course, certain sympathies for his benefactor, which would have been moral lights upon his way.

"Regrets, however, are now unavailing; what we would arrive at now is the best means of evincing our estimation of the services of the late William James, who was, in our opinion, the true 'Father of Railways.' His great competitor, George Stephenson, adopted the paternity; and far be it from us to undervalue by a hair's weight the benefits his wonderful ability conferred, not only upon this country, but many others; nay, to depreciate him would be injuring the reputation of James, of whose claims on the British public we are unhesitatingly the advocate; for when the former was but a struggling uneducated man of genius, the latter was spending fortunes on the advancement of mining and railway interest, and indoctrinating those engineering principles whereon the commercial prosperity of the United Kingdom is mainly founded.

"We have had submitted to us a letter of Mr. James, written in the year 1822, and addressed to Mr. Losh, of the firm of Losh, Bell, and Company, Newcastle, in which this paragraph occurs—'I wrote to Mr. Stephenson, to request his father to consider the best form and mode of engine power and carriage for conveyance of passengers and light goods, with the utmost dispatch, between these towns' (Manchester and Liverpool). Here, again, is afforded evidence of the precedence this project had in the mind of James as compared with the design of Stephenson, who estimated the acquirable velocity at only three to four miles on the level, and ten miles as the maximum running down an available incline.

"The Government of a country like this, so vast in its resources, so much indebted to engineering for its dominant position, so responsive in benevolence when its sympathies are legitimately appealed to, should turn no deaf ear to the claims put forward by the surviving representatives of William James. The day is now past for procrastinating, and whatever it may appear desirable to do should be done quickly; to palter with demands for assistance, when they proceed from those who have been depressed in circumstances—all but reduced to penury through the unselfish zeal of a father, who wrought and wrought materially for his country's good—would be unworthy of our governing powers, and disapproved by the people.

"It may here be inquired, why has so long a time been allowed to elapse without memorializing in the proper quarter? An honest and laudable pride keeps many a worthy man mute, but years have a modifying and mellowing influence on the improvident intolerance of the spirit, and induce it to accept that staff in the evening of life it had spurned in the mid-day.

"We understand such a feeling of independence, under no very easy circumstances, either marred the intent of a committee of the first engineers of the period, with Robert Stephenson, M.P., C.E., at their head, the purpose being a general subscription for James's family. 'In consideration of their father's public services as the original projector and surveyor of the Manchester and Liverpool Railroad, and many other of the most important railroads in this kingdom, principally at his own cost. We being of opinion that the great benefits conferred upon this country in particular, and the world at large, by his successful exertions and great pecuniary sacrifices, to the injury of his family (who are thereby deprived of all patrimony), entitle them not only to public sympathy, but also compensation, it being an acknowledged fact that to their father's labours the public are indebted for the establishment of the present railway system.' So ran the text of the document sworn to before the Lord Mayor on the 24th of June, 1846.

"Can Crown, Government, or people require more assuring testimony of the worth of a man whose services they are morally bound to acknowledge by a state provision for his children?"

Meetings for the Week.

THURS.—*Inventors' Institute.*—"On the Inadequacy of the existing Courts for the Trial of Patent Causes and the Necessity for Establishing a Special Court," by H. Williams, Esq., at 8 p.m.

FRI.—*Architectural Assoc.*—Special Business Meeting, at 8 p.m.

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

All communications should be addressed to the EDITOR, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

G. H. A.—Mr. Gisborne's address is 3, Adelaide-place, E.C.

R. P.—You can continue to use your lathe without infringing the patent you refer to. There is a sad deficiency of books on turning, and, as you have already tried Holtzapfel, and found him wanting, we scarce know where to advise you to look. Perhaps Messrs. Lockwood could give you some information.

W. AUSTIN (Milford).—The style of your letter was scarcely suited to our pages. If you will kindly confine yourself to a statement of your views and what you propose, without too much animadversion on existing arrangements, which neither strengthen a cause or display good taste, we will insert a short letter. The firm of Brown, Lennox, and Co., Millwall, can supply you with information on chain cables; and Mr. Bennet Woodcroft, of the Patent Office, will forward you the specifications you want if you address a line to him.

T. W. J. (Stockton).—The simplest rule we can give you for calculating the strain your cylindrical boiler will bear. is this—Multiply double the strain allowable on the iron per square inch (which should not exceed 5,000 lb.) by the thickness of the boiler plate in decimals of an inch, and divide by the diameter of the boiler in inches; the quotient is the proper working pressure. To find the thickness for a given pressure—Multiply the diameter of the boiler in inches by the required working pressure, and the four right-hand figures of the product is the proper thickness in decimals of an inch.

Correspondence.

[*We do not hold ourselves responsible for the opinions of our correspondents.*]

◆

MARINE ENGINE IMPROVEMENT.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I have read with much pleasure your article upon Marine Engine Improvement, in your last number, and the only wonder is, that this important department of mechanical civil engineering has not made greater progress up to the present time. The great and unnecessary weight and space occupied by marine engines have long attracted the serious attention of my brother and self; and when the Royal Mail Company started, I proposed that they should adopt engines of a much lighter construction, but equally strong and effective as those which they ultimately employed. I pointed out, at the same time, the defects of the old system, and that in a very few years they would be obliged either to build new vessels with improved engines, or to take out the old engines and replace them with new engines of a lighter and more improved construction. My advice was not attended to. The old heavy side-lever engine, with great masses of cast iron, was adopted, so that the vessels scarcely attained a speed of eight knots, with a great unnecessary consumption of fuel and reduction of cargo space. As I predicted, in a very few years they were obliged to remodel their fleet upon the principles which I recommended, at a large additional outlay of capital; but, notwithstanding this, there is still considerable room for improvement.

About thirty years ago, I was consulted by the Admiralty, as to the advantage of employing steam at a higher pressure than that which they were then using—namely, 5 lb. per square inch. I strongly recommended them to employ steam of 40 lb.; and I understand that they have now got up to 25 lb. This is certainly an improvement. Still they are a long way behindhand.

You have justly instanced the locomotive engine as an example where a far greater amount of force is developed in proportion to its weight than the most improved marine engine which has yet been constructed. Some years ago, my brother and myself designed and constructed engines for one of the royal yachts, the "Elfin," of the nominal power of 40 horses; but which worked up to the indicated power of 254 horses; whilst the total weight of the engine and boilers, with water, was only 30 tons. These engines, although light compared to those hitherto employed, may be much improved, and with steam of much higher power a far greater result will be obtained.

I trust, therefore, that you will pursue this important subject, for a wide field is open to those who are ambitious to excel in the advancement of steam navigation.

I am, your humble servant,

London, June 16, 1863. JOHN RENNIE.

Miscellanea.

A memorial has just been presented to the Lords of the Admiralty by the Northumberland colliery proprietors, and they state that trials have been made, and it has been found that when North and Welsh steam coals are burned together in equal proportions, or with one-third of the latter to two-thirds of the former, no smoke is emitted. Mr. W. S. Lindsay, M. P., confirms the statement of the memorialists, and the Lords of the Admiralty have consented to make experiments with the view of accertaining the practical results of using North in combination with South Wales steam coal.

At a recent meeting of the Liverpool Dock Board, a report from the Marine Surveyor on some experiments made with petroleum was read. From this it appeared that the oil burned for ten minutes, giving a good flame, when an explosion took place, blowing the lamp to atoms. The lamp used was the ordinary lighthouse lamp as at present in use, and the disaster is partly to be attributed to the fact that the lamp in question was unsuited for the description of oil to which it was applied; but partly also, we should think, to neglect of testing the oil and the use of too volatile a quality of it. The degree of heat, however, may be so great as to render all such oils improper for such a purpose.

Sir Charles Trevellyan in his last budget wisely leaves to our Cheshire manufacturers the future supply of salt to India. Thus another of the few remaining relics of the old Company is gone, and we have a large increasing market permanently opened, to the great advantage of the salt trade, to the port of Liverpool, and to shipowners, to whom the carriage of 300,000 or 400,000 tons of salt is, most beneficial. This important result is in a great measure, due to the untiring efforts of the Salt Chamber of Commerce, seconded has they have been so ably and energetically by the members for South Cheshire.

Letters from Tripoli report that a company of French merchants established there have just entered into arrangements with a Manchester company for the cultivation of cotton on a large scale. A considerable extent of land is taken for four years, and a good breadth of cotton is already in the ground.

The "Charger" gunboat is ordered to proceed from Portsmouth to the Thames, where it will be placed in Messrs. Young and Magnay's dock, and fitted with a new description of propeller, patented by Mr. Curtis, of London, and from which great results are confidently predicted. The principle of the new propeller is an application of the universal or "shoulder" joint, by means of which the rudder and propeller are always in a parallel line. The inventor claims that by these means a ship will be able to describe a circle in little more than her own length, and all vibration from action of the backwater upon the rudder is effectually done away with. The difference between the new principle and the old is precisely the same as that which exists between the railway carriage with its fixed wheels and axles, and the ordinary road carriage with its pivoted axle and wheels.

The new cupola screw armour-clad man-of-war, launched by Messrs. Robert Napier and Sons, Glasgow, for the Royal Danish Navy, on the 6th of last month, after a most expeditious fitting out, came down the river on Friday last and proceeded to Gareloch to test her speed and have her compasses adjusted. She was under steam, assisted by only one tug, the "Chesapeake." After passing this the tug was thrown off and she steamed across to the loch herself. Her qualities as to speed tested thus far were of the highest order. She was sailing very fast and even distanced the tug, which is well known as a fast-sailing and excellent steamer. She then proceeded up the loch to run the measured mile. The "Rolf Krake," by which name she has been christened, is of very peculiar construction, being low in the water and of considerably greater breadth than is usual for vessels of her length. She is built from plans approved by Captain C. P. Coles, the inventor of the cupola war-ship. Her length is 185 ft., breadth 33 ft., depth 14½ ft., tonnage 1,246 tons. Her engines are of 240-horsepower. She is only some 5 ft. above the water line, with bulwarks to fold down in action, and she displays two revolving cupolas rising 4½ ft. above the deck, and 21 ft. in diameter. She is armour-plated from stem to stern, the plates being 4½ in. in thickness, and increasing to 7½ in. at the port holes, with the addition of 9 in. of teak lining inside. Her armament will be four 68-pounders—two in each tower, worked from the inside. The deck is entirely clear of obstruction, excepting the funnel and a small fixed tower aft for steering the vessel; in fact, the whole work is done under cover of armour plates, and she appears as one piece of solid iron from stem to stern.

One of the most novel of all public commercial companies is advertised in the Parisian journals--viz., La Compagnie Generale des Chiffons de Paris—a company to buy the produce of the street scavengers who pick up paper, rags, bones, broken glass, &c., in the public thoroughfares of that capital. The prospectus says that 25,000 people live by this strange trade.

The cost, amounting to £600, of the Bude Haven, Cornwall, new lifeboat establishment, has been presented to the National Lifeboat Institution, by the surviving children of the late R. T. Garden, Esq., of Rivers Lyons, Ireland, as a memorial of their beloved mother, Mrs. Elizabeth Moore Garden. An inscription recording this philanthropic gift has been beautifully carved in stone and placed over the doorway of the lifeboat house. The lifeboat is 33 ft. long, and rows 10 oars, double-banked.

There is a weed called the *sida retusa*, which grows wild in unfrequented streets and vacant places at Brisbane, in Eastern Australia, and was looked upon there as a pest. This weed has been found to yield a valuable fibre, and £30 a ton for 3,000 tons have been offered for it for shipment to England.

Mr. Cave, M.P., chairman of the West India Committee, has received a letter from Jamaica containing a scheme which has caused great interest in the island, for using rum, instead of spirits of turpentine, in the preparation of paint. The present price of turpentine is 10s. a gallon; that of rum in bond from 1s. 4d. to 2s.; but the duty amounts to 10s. 2d. in addition, and it is suggested that rum rendered unfit for drinking, either by a mixture of creosote or naphtha such as is now used in methylating spirits of wine, might be admitted duty free as a desiccant of paint, for which it has been proved by experiment to be well fitted. The revenue would not suffer, as the spoilt rum would come into competition with a duty-free article, and considerable relief would be given to the painting trade, which is in many places almost brought to a stand by the high price of turpentine. It is understood that Mr. Cave has brought the question before the proper authorities, and that it is still under consideration.

The Institution of Mechanical Engineers will make Liverpool the seat of their next annual congress. The meetings will take place in the first week of August; and an influential local committee, of which the late Mr. W. F. Macgregor was chairman, and Mr. W. Stubbs, C.E., hon. local secretary, met on Wednesday last in the committee-room of the Free Library, granted by the Library and Museum for the purpose. Mr. James Kennedy presided at this meeting, and preliminary arrangements were so far made. From these it appears that the London and North-Western Railway Company have liberally offered to place a special train gratuitously at the service of the Institution on Thursday and Friday, on which days it is intended to visit various works at St. Helen's, Messrs. Pearson and Knowles' Colliery at Wigan, the Railway Works at Crewe, and a Salt Mine at Northwich. The mornings of the first two days will be devoted to the real work of the Institution—reading papers upon scientific subjects in the Concert-room, St. George's-hall, which has been kindly granted for the purpose. The afternoons of each day will be spent in visiting various engineering works and places of interest in the town and upon the river. Among other attractions, Colonel Clay has invited the members to lunch at the Mersey Forge.

Gas Explosion at Blast Furnaces.—The *Birmingham Daily Post* says:—With a view to economize the consumption of fuel beneath the boilers at blast furnaces, certain makers of pig iron have adopted a plan for bringing down from the top of their furnaces certain combustible gases, that would otherwise go to increase the volume of flame issuing from the mouths of the huge structures peculiar to every iron-making district. The plan pursued is to insert a pipe of huge proportions, riveted together, as in the manufacture of a boiler, into the furnace near to the feeding gallery surrounding the summit, and to bring it down, after making a short elbow, almost perpendicularly by the side of the furnace. Through these pipes the gases are conveyed to the fires beneath the boilers. Unless care is used in the working of the apparatus, accidents are likely to happen, inasmuch as, with certain mixtures, the gases become explosive, and explosions not unfrequently occur. Such an accident happened yesterday morning at the Osier Bed Furnaces, near Wolverhampton, where, among other works in that district, the apparatus in question has been adopted. Here, at about half-past six in the morning, the monster pipe we have described was rended by an explosion of the gases passing through it, and a portion of the machinery attached to it was detsroyed, but no personal injury was sustained. The Osier Bed Furnaces being the property of Messrs. Sparrow, and the accident having happened near to the scene of the fatal boiler explosion which occurred last Saturday week at the finished ironworks of Messrs. W. and J. S. Sparrow, rumour attached larger proportions to the occurrence than it deserved. For some time there was a little alarm in the immediate district surrounding the furnaces; the consequences were happily not of a serious character.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 3079, 3081, 3121, 3128.
Boilers and Furnaces, 3109.
Ships and Boats, including their fittings, 3105, 3119.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 3076, 3083, 3096.
Cultivation of the Soil, including agricultural implements and machines, 3090.
Food and Beverages, including apparatus for preparing food for men and animals, 3113.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 3073, 3077, 3078, 3087, 3097, 3112, 3117, 3120, 3124, 3125, 3127.
Buildings and Building Materials, 3080, 3110, 3116, 3126.
Lighting, Heating, and Ventilating, 3072, 3093, 3099, 3104, 3108, 3123.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 3068, 3069, 3070, 3071, 3075, 3086, 3089, 3092, 3098, 3100, 3101, 3103, 3114, 3122.
Metals, including apparatus for their manufacture, 3094, 3106.
Chemistry and Photography, 3085.
Electrical Apparatus, 3074, 3095.
Warfare, 3084, 3091.
Letter-Press Printing 3111.
Miscellaneous, 3082, 3088, 3102, 3115.

3068. W. H. Andrew. *An improvement in scissors and shears.* Dated November 14, 1862.

This invention consists in fitting to the nail or back end of the blades of scissors and shears a clip spring in the form of a V or part of a V, the fore ends or end of which are or is attached to or secured by the screw or pin whereby the blades are united or otherwise. The object of the spring is to ensure contact of the cutting edges from heel to point when the scissors or shears are being used. *Patent completed.*

3069. S. Roberts. *An improvement in frames for containing stoppered bottles and jars.* Dated November 14, 1862.

This invention consists in fitting to frames for holding stoppered bottles or jars arms (moveable as hereafter described) over the stoppers of the bottles or jars held in the frames so close to them that the stoppers cannot be raised sufficiently to remove them from the bottles or jars; nor can the bottles or jars themselves be removed from the frame as long as the arms remain over the stoppers. The inventor applies a spring or other lock to a collar from which the arms project, and on opening the lock the arms are free to be moved into a position between the stoppers, when they, as well as the bottles or jars, may be removed from the frame. Instead of an arm being made to extend over every stopper, one arm may be carried out on each side of a frame, and a rod secured by lock may be fitted to each arm, which rods shall extend over the stoppers, and answer the purposes of the arms as hereinbefore described. The rods may be straight or circular or of other form to correspond with the shape of the frame. *Patent completed.*

3070. H. Morgan and J. Parkinson. *Improvements applicable to weighing machines, parts of which may be used to measure liquids.* Dated November 14, 1862.

This invention, when applied to weighing machines, consists in placing the counterpoise in a suitable vessel containing spirit, water, oil, mercury, or any other suitable fluid, and to which is attached a peculiar description of self-acting fluid indicator. *Patent abandoned.*

3071. V. J. Cassaignes. *Improvements in stereoscopes.* Dated November 14, 1862.

This invention consists, essentially, in producing the coloration of the stereoscopic image by means of a transparent coloured surface interposed between the picture and the eye of the observer, in such a manner that this presents two or a greater number of different tints. This improvement can be applied to all sorts of stereoscopes, and the inventor names chromo-stereoscopes all stereoscopes provided with it. *Patent abandoned.*

3072. C. Binks. *Improved methods of, and apparatus for, treating linseed and other oils and fats.* Dated November 15, 1862.

We cannot here give space to the details of this invention. *Patent abandoned.*

3073. J. S. Clegg and J. Slater. *Certain improvements in carding engines.* Dated November 15, 1862.

This invention consists in a novel arrangement and adaptation of mechanism for effecting the reciprocating motion to be given to the doffing comb. The doffing comb is secured at one end of a horizontal rod or lever, having a fulcrum at a convenient point between its extremities; the opposite end of this lever is furnished with a bowl or roller, which runs in an undulating or snail groove, that is, having a number of elevations and depressions formed in a disc or plate, so that, as this grooved disc rotates once round its axis, the doffing comb may be caused to vibrate any number of times, according to the number of elevations and depressions in the groove. *Patent abandoned.*

3074. L. Croc. *An improved ink to be used for the purpose of electric telegraph printing or marking.* Dated November 15, 1862.

The inks which the patentee has contrived to compose have the following properties:—They dry rapidly on paper, keep the inking plug or roller damp for one or more days, and yet do not dirt it. They have no corrosive action whatever on the metallic parts of the apparatus. They are solutions and not colouring matters in suspension in a liquids. Colouring matters: The patentee claims the use of all colours derived from aniline, which colours are three in number—red, violet, and blue. These colours he uses either separately or conjointly. Dissolvents: As dissolvents of the said colouring matters, he claims the use of the following liquids, viz.:—All bodies pertaining to the alcoholic series, the fixed or solid oils, the volatile or essential oils, and glycerine. Thickening matters: He makes use, as thickening matters, of resin, wax, and generally of all substances which are suitable to unite with the above liquids to render them thick or siccative. Dissolutions of aniline in the above-mentioned liquids yield coloured oils, and these, like all carburets of hydrogen, are instantly absorbed by paper, which they penetrate, forming outlines of perfect neatness. This property is very precious for quick transmission. The improved inks he uses either with Morse's apparatus, or the like, or with any printing type apparatus. *Patent completed.*

3075. E. Kirby. *A new or improved pulley for tightening the cords of window and other blinds.* Dated November 15, 1862.

This invention is carried out as follows:—To a plate which is fixed vertically on the window or other frame, two horizontal arms or brackets are fixed, one near the top, and the other near the bottom of the plate. A fixed vertical rod is supported at top and bottom by the said arms or brackets. The said rod is square, or of other angular figure, and has a screw thread on its angles. The axis carrying the roller under which the blind cord passes slides on the said rod, and a screw box or nut works upon the thread on the angles of the said rod, the said screw box or nut being above the sliding-piece to which the axis of the pulley or roller is fixed. The pulley and sliding-piece to which its axis is attached are supported by the blind cord which passes under the pulley, while they are prevented from rising by the screw box or nut. In order to tighten or slacken the blind cord, it is only necessary to turn the screw box or nut on the rod, when it rises or falls on the said rod, and forces down the sliding-piece carrying the axis of the pulley, or permits the said sliding-piece to rise. *Patent completed.*

3076. J. Rimmer. *Improvements in Hansom cabs.* Dated November 15, 1862.

The main objects of this invention are to prevent, or reduce to a minimum, jolting and vibration of the body and shafts, and parts thereto attached, of Hansom cabs, and to bring the horse nearer to the body of such Hansom cabs than has been practicable hitherto, and thus make them easier of traction or movement. To the body of the cab, close to the heel board, the inventor fastens a pillar or spindle, which he carries upwards through the curved or otherwise-formed hind part of the shafts, or through or between a shoulder or shoulders an eye or eyes or their equivalents thereto attached. On the said pillar or spindle he places one, two, or more helical or spiral springs, part of which is below and part above the shafts or shoulders or eyes thereon, and a sufficient number of nuts and washers or other arrangement for keeping the said springs in their places. The shafts are jointed by a pin or otherwise to fixed or rigid stays, so that, when the tyre of a wheel passes over a stone, or anything above the level of the road, or into a rut, or any place under the level of the road, the joints allow the shafts to move and maintain the same relative position to the horse, and the helical or spiral springs above and below the ends of the shafts receive the shock, and relieve the body of the vehicle from the sudden jolt and subsequent vibration so disagreeable in all Hansom cabs now made. The rigid stays to which the shafts are jointed or coupled do not require (when helical or spiral springs such as those already described are used) to be carried so far forward as in those Hansom cabs where springs are not used, nor as in those with long flat springs; consequently the horse can be brought back close to the bow of the shafts and to the body. *Patent abandoned.*

3077. A. and H. Illingworth. *Improvements in washing wool and other fibres.* Dated November 15, 1862.

In the washing of wool and other fibres, various means have been resorted to for carrying the fibre through the wash liquor, and amongst others it has been proposed to employ blades or plates applied to endless travelling bands or chains; but it was found that the tendency of such blades, by the continuity of their surfaces, was to produce a felting or matting effect. These improvements consist in substituting for such blades or plates prongs or teeth or grates, which may be of a curved or other suitable form, adapted, when applied to continuous travelling surfaces, or when in operation upon the fibre, to be continuously travelling in the same direction to carry forward the fibre through the wash liquid, and facilitate the washing thereof without felting or matting it. They also apply a series of prongs to the feed end of the wash trough to act as guides or conductors to facilitate the complete immersion of the fibre in its passage to the series of prongs, teeth, or grates. *Patent completed.*

3078. G. Sugden, J. Briggs, and J. Lockwood. *Improvements in means or apparatus for spinning wool, mohair, alpaca, and other fibres.* Dated November 15, 1862.

The object of these improvements is to give facility for the spinning together of fibres of different lengths of staple. For this purpose the inventors employ additional back rollers, one pair or set of back rollers being placed at a distance from the front rollers adapted to the longer length of staple, and another pair or set of back rollers at a distance from the front rollers adapted to a shorter length of staple. The roving of the longer length of staple presses between the back rollers farthest from the front rollers, and the roving of the shorter length of staple between the back rollers nearer the front rollers, and the two rovings then pass together to the front rollers to be spun together. They find it convenient to drive the back rollers conducting the roving of shorter staple in the opposite direction to those for the longer staple, and to pass the roving thereto first over and then between them. *Patent abandoned.*

3079. E. N. Duru. *An improved motive power engine.* Dated November 15, 1862.

This consists in employing mercury and water as the motive power, either separately or in combination in a specially constructed machine. *Patent abandoned.*

3080. H. B. Whitburn. *An improved material to be used in the manufacture of glass, and for other purposes where silica is used.* Dated November 15, 1862.

This improved material is sand, such as is found in this country; it is treated as hereafter stated. The sand to be treated by calcining or roasting it, which may be effected in a variety of ways; for instance, in the open air, or in close stoves, ovens, or in heat chambers or vessels. *Patent abandoned.*

3081. H. James. *Improvements in steam engines.* Dated November 15, 1862.

These improvements in steam engines consist—1, In the means of generating steam for the working of steam engines generally, more especially of very high-pressure steam for actuating engines hereafter described. The patentee effects the generation of steam by the injection of water, either in the shape of finely-divided spray or otherwise, into circular, square, or other shaped interstitial, vesicular, or cellular slabs or plates of metal, which he prefers to be composed of the best wrought iron. The internal cavities in these plates are united together by tubes or suitable projections thereon, which may be used also for regulating their distances apart from each other when placed over a fire in a suitable furnace. These hollow slabs or plates of metal have series of apertures or tubular openings through them in the direction of their thicknesses, to allow the smoke or other heated products of combustion arising from the fire after having impinged against their surfaces to pass through them into a chimney. These interstitial slabs or hollow plates may be formed of thin metallic plates, united together by series of very short tubes passing through them in the direction of their thicknesses, forming so many openings for the passage of smoke through them, and riveted or welded thereto, and to suitable pieces of metal placed between and around their outer edges, or may be properly moulded and formed in cast iron or other more suitable metal or compound of metals; or they may be otherwise formed by the drilling of holes through solid metallic slabs or plates in a parallel direction to their horizontal surfaces, and made to cross each other, so as to unite the several cellular passages so formed together, leaving, at the same time, sufficient spaces between these numerous intersections to admit of apertures being made through such slabs in the direction of their thicknesses for the passage of smoke, the end openings of the perforations around the edges left by the drilling being plugged and welded, or otherwise closed perfectly steam and water-tight. The invention consists—2, In an improved method or means of applying very high-pressure steam through the medium of water to the working of engines, which improved method constitutes a material modification of a portion of a former invention patented by the present patentee, bearing date the 4th day of September, 1855. *Patent completed.*

3082. J. Wilson. *Improvements in hydraulic pumps.* (A communication.) Dated November 15, 1862.

This invention consists—1, In injecting water by means of one or several pumps under a piston or ram loaded with weights, which the patentee terms a compensator, to form a self-acting hydraulic pressure, which can, in proportion to its size, be employed to feed any number of hydraulic presses. 2, In the peculiar arrangement of working the valves of the pumps. *Patent completed.*

3083. G. Gray. *Improvements in the manufacture of wheels.* Dated November 15, 1862.

For the purposes of this invention, a peculiar construction of metal nave is used, by preference of cast iron. Each nave is cast in two parts, in one of which the several mortises or sockets for the inner ends of the spokes are formed, and such sockets or mortises are made, by preference, with parallel sides, the mortises radiating from the centre of the nave. It is preferred that the angular parts of the nave which come between the spokes should be cast hollow, in order to obtain lightness. The second, or outside part of the casting simply consists of an outside cover to the nave, which is fixed to it by means of screws, the ends of which screw into an interposed disc or flat ring of wrought iron, and this disc or ring is fixed to the first-mentioned part of the casting by means of screw bolts and nuts, the heads of which bolts are countersunk in the disc or ring, and the screw bolts pass through holes through the angular parts of the casting which come between the spokes. In putting a wheel together, the wrought-iron disc or flat ring is put into its place, and so that it does not come in contact with the casting, but is held by moveable pieces a short distance away from it; the screw bolts are then passed through the ring and the casting, the nuts are then screwed up, and the ends of the wood spokes are driven into their places, the tenons being slightly taper. The flat ring or disc does not fit close around the cylindrical central part of the casting of the nave against which the inner ends of the spokes come when they are driven home, and the fact of their being driven home will at once be seen through the openings in the centre of the ring or disc. The spokes having been driven into their places, the outer plate is put into its place and fixed by screws to the wrought-iron disc. Should the inner ends of the spokes shrink, the disc may be tightened by the nuts. *Patent completed.*

3084. F. Palmer. *Improvements in projectiles.* Dated November 15, 1862.

This invention relates to a novel mode of constructing hollow projectiles, such as shells or projectiles to answer the purpose of canister or grape-shot. The object of the invention is—1, to construct a hollow projectile in such a manner that its flight shall be true and not erratic; and that, whatever the range may be, the projectile shall strike the object with the point or fore end foremost. This latter object is effected by distributing the weight of the projectile in such a manner that the fore end or forward half of it (except bomb shells, which must be spherical) shall contain a large excess, say about two-thirds, of the entire weight of the projectile. Another part of the invention consists in constructing the projectile of a series of single rings or compound rings, composed of two, three, or more single rings arranged and formed in such a manner that, on the projectile exploding, the rings shall be subdivided into a large number of pieces of nearly equal dimensions, and of such a weight that any piece by its mere gravity or weight when falling from a height, will be sufficient to kill or seriously injure a man. *Patent completed.*

3085. C. Binks. *Improved methods of obtaining oxygen and chlorine gases.* Dated November 17, 1862.

We cannot here devote space to the details of this invention. *Patent abandoned.*

3086. F. Raules. *Improvements in envelopes with the view to affording better security thereby.* Dated November 17, 1862.

This invention is carried into effect as follows:—The envelope, except as hereafter stated, is to be cut or formed in the usual fashion, by adopting flaps brought together and meeting in or near the centre, where the same are secured together. That flap, however, which is folded over the others, and is to be next to the letter or missive, is to be provided with one or more small tongues or projections (one in the centre being the most likely of adoption), the said projection or tongue, or projections or tongues, to be covered with adhesive composition on both sides by preference, so that, upon wetting the same as usual (the letter or missive having been inserted in the envelope), the tongue or tongues may be secured to the letter or missive, and to the envelope. The two other flaps next to the aforesaid flap may each be provided with a similar projection, tongue, or tongues, serving the same purpose. The topmost or opening flap is also to be provided with a small tongue or flap, which may be of ornamental shape, and of lacework, open work, or notched and covered inside with adhesive composition, the same to be wetted and secured to the outside of the envelope, the place where it is to be secured being by preference coloured, so as to be discoloured if wetted, in order to prevent the envelope being opened by steaming or wetting, without evidencing the same by injuring the lacework or open work, or by discoloration. It is evident that, to open this envelope, the last-mentioned flap must be opened, the flap detached from the tongue or tongues, and (if these be wetted on both sides) also detached from the letter or missive, before the same can be abstracted from the envelope; and, as the letter or missive when opened will adhere to the envelope, the two will remain together for evidence. *Patent abandoned.*

3087. W. Dobson. *Improvements in lace dressing frames employed in the dressing of lace or other fabrics.* Dated November 17, 1862.

In carrying out this invention, the inventor covers or protects the pins in the following manner:—He employs a strip or piece of wood, or other convenient material, of any required size and shape. This strip or piece he covers with flannel or other suitable material. The strip or piece thus or similarly covered, he places over the pins before mentioned, by which means he entirely prevents the possibility of injury either to the rollers or to the pins. The pins so covered will require to be washed less frequently than heretofore, and there will be less liability of the fabrics being damaged while being dressed. *Patent completed.*

3088. D. Thompson. *Improvements in screw cocks.* Dated November 17, 1862.

This invention has for its object the arrangement of the valve gear in screw cocks in such a manner that the joint between the thrust collar on the screw spindle and the surface of the valve box cover is rendered more or less perfectly water-tight, both when the valve is closed, and when it is open, thus enabling us to dispense entirely with the packing and gland usually employed for rendering the passage of the screw spindle through the valve box water-tight. *Patent abandoned.*

3089. W. Williamson. *Improvements in washing, wringing, and mangling machines.* Dated November 17, 1862.

This invention consists in simplifying the construction of washing, wringing, and mangling machines that are actuated by a crank or eccentric for the washing apparatus, and rollers for the wringing and mangling apparatus. Each process has hitherto been actuated by separate means—that is to say, the washing by means of a crank, actuating a reciprocating lever; and the wringing and mangling rollers by a separate arrangement, or by means of a series of toothed wheels—either apparatus for washing, wringing, and mangling being put in and out of gear as required. By these improvements the patentee abridges several pieces, and simplifies the machine for washing, wringing, or mangling. He makes the spindle which is turned to actuate the machine, and on which is the handle—or, if driven by power, on which is the driving pulley—the axis of one of the wringing and mangling rollers, and this roller will always rotate, whether using the machine either for washing, wringing, or mangling. A second roller supported in guides at its ends being under the top or actuating roller is brought in contact with the same when required for wringing or mangling, by turning a screw or screws that press on a spring or springs, or by an arrangement of weighted levers, and can be released from contact by lowering the same by means of the before-mentioned screws or levers. If the machine is required for washing only, it is necessary to place the end of the connecting-rod over the crank pin, and insert a cotter or pin in the holes at the end of the same, and lower the bottom roller out of contact with the actuating roller. If the machine is required for wringing or mangling, the patentee withdraws the cotter or pin, lifts the connecting rod off the crank pin, and turns the two screws, or releases the weighted levers that raise the lower roller, as before described, and the machine is then ready for wringing or mangling. *Patent completed.*

3090. C. Littleboy. *Improvements in implements for cultivating land.* Dated November 17, 1862.

The principle of this invention consists in the adaptation and attachment to any ordinary plough (whether worked by animal or steam power) of an instrument which breaks up the subsoil without turning it, and without interfering with the simultaneous action in the ordinary way of the plough upon the surface above the subsoil, such instrument being removeable from the plough at pleasure. *Patent completed.*

3091. G. Richards. *Improvements in the construction of ordnance and firearms, and in the projectiles to be used therewith.* Dated November 17, 1862.

This invention has reference to a previous patent granted to the inventor for a projecting rifling; and the inventor, in the specification of the present invention, shows how the same may be further developed by the adoption of various descriptions of projectiles suitable thereto, in such manner that the projectiles shall not derive their rotary motion by means of grooves or channels cut therein, as in the former invention, but that they shall be made so as to simply bear upon the surfaces of the projecting rifling, and thereby derive the requisite rifle motion from its spiral form or curve during their passage through the gun, whether a piece of ordnance, a rifle, pistol, or other firearm, to all of which the invention is equally applicable. Thus the projectiles may, in some cases, be made perfectly smooth on the exterior, and without either studs or grooves thereon, and they will be made to fit truly or evenly against the surfaces of the projecting rifling. *Patent abandoned.*

3092. J. Raphael. *Improvements in umbrella, parasol, sunshade, and walking sticks.* Dated November 18, 1862.

This invention consists in obtaining the above-named sticks from any wood cut from planks longitudinally with the grain, in lieu of from branches or off-shoots of trees, and twisting or bending the same in forming the handle or otherwise by steeping or soaking the ends thereof, firstly, in a warm solution of soda and water, and, subsequently, by means of heat applied thereto through the medium of a jet of gas or otherwise. *Patent abandoned.*

3093. J. Arbos. *Improvements in generating certain gases for lighting and heating, and in apparatus employed therein.* Dated November 18, 1862.

This invention consists—1, in the formation, as hereafter described, of a gaseous compound, and in mixing it, in retorts heated to a red heat, with gas arising from the distillation of coal or from the decomposition of fixed or volatile oils, resins, tars, or fatty bodies, to manufacture gas suitable for lighting and heating; and 2, in an apparatus for generating the gaseous compounds. The apparatus consists of a furnace lined with fire-brick, and by preference in the shape of an inverted cone with a circular grate at bottom, through which air, supplied by a blast, is admitted from a pipe below, its admission being regulated by a tap. There is a conical vessel, with opening at top, placed on the mouth of the furnace, through which coal or other fuel is introduced, and by which gas is allowed to escape at the commencement of the operation. As soon as inflammable gas is produced, the opening is closed by a conical stopper. A syphon tube passes into the furnace, through which tar, oils of resin, of schist, of petroleum, or liquified fatty matters are introduced when required. The gas generated in the furnace passes off by a tube from the upper part of the furnace into ordinary retorts, in which coal or oil gas is being generated. From these retorts the gaseous mixture passes through the condensers and purifiers to the gas-holders. *Patent completed.*

3094. P. N. Klein. *Machinery for turning or shaping metals or other substances.* Dated November 18, 1862.

This invention consists in the employment of machinery, as described with reference to the drawings, in combination with an ordinary turning lathe for shaping metals and other substances square or polygonal, instead of round or oval as hitherto. *Patent completed.*

3095. W. H. Burnett. *Improvements in the mode of working telegraph lines, and in instruments and apparatus employed for telegraphic purposes.* Dated November 18, 1862.

An extension of time for filing the final specification of this invention having been petitioned for, the documents relating to the invention cannot at present be seen.

3096. E. P. Houghton. *Improved application of breaks or apparatus for retarding or stopping railway carriages.* Dated November 18, 1862.

This invention consists in a partial displacement or disconnection of the engine or break van, either or both, or any other portion of the carriages forming the train, whereby the engine, break van, or other portion or portions of the train thus partially displaced or disconnected, sets in motion a break or breaks, or other appliances, which, acting on the wheels or other parts of the train, thereby impede its progress. *Patent completed.*

3097. C. W. Harrison. *Improvements in looms for weaving.* Dated November 18, 1862.

This invention relates to certain peculiar constructions and arrangements of apparatus for giving the necessary motions to the various moving parts of looms by pneumatic pressure, without requiring the intervention or complication of the parts ordinarily employed, and is carried out as follows:—1, The sley beam is actuated by means of connection with the piston rod of a cylinder, which communicates with a reservoir of compressed air, the air being admitted into the cylinder by suitable arrangements of valves, as in the ordinary steam engine. 2, The sley beam is constructed so as to move in a horizontal plane, each end working in a groove formed in the cheeks of the frame, and to avoid friction it is carried on wheels or rollers. 3, By means of suitable connections with the piston of the air cylinder which actuates the sley beam, the heddles receive their proper motions. 4, Motion is given to the shuttle by the direct action of compressed air, without the intervention of pickers and divers, as heretofore. This is effected by forming an aperture or chamber at each end of the sley beam, wherein the shuttle can wholly or partly enter, and by making an aperture in each check of the frame to which by proper connections compressed air is conveyed. As these apertures are brought opposite to each other by the motion of the sley beam, a suitable arrangement of valves is made to admit compressed air which shoots the shuttle. To reduce friction in the motion of the shuttle, the patentee forms the ends of the race of glass, porcelain, or other similar material, to which a smooth or polished surface is given; or he cases the shuttle therewith. To economise the propelling power, he sometimes construct the ends of the race of a tubular form, with a longitudinal opening for the passage of the weft. And 5, The motions for letting off the warp and winding on or taking up the fabric, are obtained by suitably formed connections with the piston of the air cylinder that actuates the sley beam. *Patent completed.*

3098. C. Neild and J. Hopkinson. *Improvements in fire-alarums and indicators of temperature.* Dated November 18, 1862.

This invention consists in the mode of starting an alarum when a room or building is on fire, by the consequent increase of temperature of the surrounding atmosphere. Within the building or room is placed a suitable vessel containing a fatty substance, or an alloy which retains a ball or weight; when the temperature of the building arrives at a certain number of degrees, the fatty substance or alloy will melt, and release the ball or weight. The base is so arranged that, when released, it runs down an inclined tube turning on a pivot or other suitable apparatus, and by turning the tubes on the said pivot releases a catch which retains a coiled spring or weight previously wound up, and thus starts certain mechanism to strike a bell, gong, or other alarm. *Patent completed.*

3099. R. Brown. *Improvements in warming and ventilating, more especially applicable to buildings, carriages, and ships, and in apparatus to be employed for that purpose.* Dated November 18, 1862.

This invention consists in ventilating buildings, ships, carriages, or other confined spaces by the employment of a light, which may be gas, or any other suitable light enclosed within a glass or glasses. If two be employed, a jacket will be formed between them. The light is supported by the vitiated air of the room or other confined space. *Patent completed.*

3100. N. Thompson. *Improvements in apparatus for* *stopping bottles, jars, and other vessels.* Dated November 18, 1862.

For the purposes of this invention the patentee employs a plate or disc of metal, or other rigid material, which by a screw is forced down on to the top of the neck of the bottle, jar, or vessel, a disc of some suitable compressible material being, however, interposed between the two surfaces. The neck of the vessel is made, by preference, cylindrical exteriorly for a short distance down, and in this portion of the neck a groove is made all round. To the neck thus formed a piece of sheet metal is applied, so as to extend half round the neck, and this strip of metal has its upper and lower edges turned inwards, so as to form flanges. The lower flange of the strip of metal enters the groove in the neck of the bottle, whilst the upper flange comes just above the top of the neck. This flanged strip of metal is secured to the vessel by another narrower strip of metal soldered or attached to it at the two ends, so as to form a ring encircling the neck, and this ring is lodged in another groove in the neck of the vessel, and prevented turning on the neck by teeth or transvere grooves being formed therein, into which portions of the ring are caused to enter, the ring being suitably indented for the purpose. *Patent completed.*

3101. R. Beck. *Improvements in reading-glasses and magnifiers to be simultaneously used with both eyes.* Dated November 18, 1862.

According to this invention the patentee makes a binocular reading-glass or magnifier by dividing a lens into two equal parts, and mounting the two parts at a short distance apart in a frame, but without in other respects altering the relative positions of the parts, except that with the highest power. He prefers to incline each part outwards to some extent, so that the axis of each half lens may be inclined in the direction of the object. *Patent completed.*

3102. J. Oxley. *Improvements in apparatus for separating liquid from substances.* Dated November 18, 1862.

The substances to be operated on are placed in an airtight vessel, made of iron, copper, or other material. The patentee connects an air-pipe to this vessel, and forces atmospheric air into the top part thereof; the air being thus compressed above the semi-fluid substances, gradually drives the latter through a pipe leading from the lower part of the vessel to a wooden or metal box or chamber placed near. In this box or chamber is a number of cloths folded like bags, having wire sheets or perforated plates, or both, between them, so that each pair of cloths is separated from others by the wire sheets or perforated plates. The effect of this arrangement is that the semi-fluids flow under the pressure of the compressed air into the centre of the cloths or bags, and by means of this pressure the liquid is expelled through the texture of the cloth, so that it runs away by the wire sheets or perforated plates, and out through the bottom of the box, leaving behind the solid residuum in the cloths. *Patent completed.*

3103. L. Lenzberg. *Improvements in the apparatus for raising and lowering Venetian and other blinds.* Dated November 19, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3104. H. J. F. Marmet. *Some improvements in the construction of lamps.* Dated November 19, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3105. J. Chalmers. *Improvements in the use, combination, and application of iron and timber, as armour for vessels of war and fortifications.* Dated November 19, 1862.

This invention is carried out as follows:—Commencing at the skin or side of the ship or wall or outer surface of a fort or work to be protected by armour, the patentee first applies what in the provisional specification of this invention is termed a cushion of timber planking, or other elastic or yielding substance, in order to lessen the rigidity of the structure, and to prevent the injurious effects of vibration caused by the impact of projectiles on the armour plates from destroying the frame and fastenings of the ship or fort, or the fastenings of the armour plates. Outside of, and covering, the said cushion, he attaches an outer plate or skin, which may be more properly termed an intermediate or second armour plate, which, when secured to the side of the ship or fort, will form a surface on which the compound backing hereinafter described will bear. This compound backing consists of alternate layers of timber planking and iron and steel ribs or plates, built up outside of the said armour plate. One of the edges of the said layers bears against the plate, whilst the other edge is presented as a support or backing for the outer or principal armour plate. He proposes that the said layers be bolted together laterally; and in order to secure a united body, and to facilitate the construction of this compound backing (especially when following the curved lines of a ship), he proposes in binding the said layers together to use bolts in short lengths with coupling nuts, which, nuts shall be of sufficient depth, not only to screw up the bolts which unite two or more layers together, but also to receive the ends of other bolts or lengths of bolts, which, in turn, after passing through two or more layers, shall in like manner be screwed up, and so on until the desired surface be covered. The ribs of iron may be plain plates of the size required, or of such a section as would tend to bind the layers together, so that when force was applied to their edges, they would act as a united body in resisting it. The planks in either case would be made to fit the ribs. He further proposes that the aforesaid layers be put together with an adhesive substance between them. The aforesaid compound backing as it is built up can be attached to the ship or fort by bolts in the ordinary manner, and the outer surface thereof formed by the edges of the planks and plates will form the bed or backing for the outer or principal armour plates. In applying these plates he would recommend that the surface of the backing and the inner surface of the plate be coated with a thin coating of india rubber, glue, or other suitable substance. In securing the armour plates to the ship or fort, he proposes to use first through bolts, with nuts and screws, either with or without a jam nut. And as the prevailing tendency of bolts subjected to the vibration caused by the impact of projectiles is to break at the thread close to the nut, rather than to strip or overhaul the thread, as frequently occurs when bolts are subjected to heavy strains, he proposes to use a shallow thread of the form generally termed a square thread, the depth thereof being only about half of the breadth. *Patent completed.*

3106. R. Mushet. *An improvement or improvements in the manufacture of cast steel.* Dated November 19, 1862.

This invention consists in adding to the materials or mixture of materials which, when melted, produces cast steel, spathose pig iron, or steel pig which has been granulated by the process of hot granulation described in the specification of this invention, whether the said hot granulated spathose pig iron or steel pig be used mixed with oxide of manganese, or the said oxide of manganese be added separately. *Patent completed.*

3107. S. S. Brown. *Improvements in elastic fabrics.* Dated November 19, 1862.

In carrying out this invention, the inventor moves the face of the framework knitting machine over its arch, then lays a thread of cotton, silk, or other material (supplied from beneath) across the needles, and fixes an ordinary jack or point machine to work in front of the frame. He then lays the points of the jack or point machine across every alternate needle, presses the points down so as to cover the beards of the said needles, drawing the jacks and sinking the frame so as to divide the loops made by the jacks, and brings the work to the needle beards, throwing the face of the frame upwards and backwards. After this he raises the points so as to enable the india-rubber or elastic thread to be drawn between the loops on the points and the loops on the needles. He then lays the elastic thread between the loops on the points and the loops on the needles, after which he brings the sinkers to the needle heads and then over the arch. Whilst going over the arch he removes the loops from the points, placing them upon the needles which the points pressed down whilst the jacks were drawn, or upon the adjoining needle when a change of pattern is required. He then removes the points from the sinkers, and places the frame ready for forming another set of loops in the following manner:—He supplies a thread of silk or other suitable material to produce the best side or outer surface of the fabric or garment, and places the said thread across the needles, then draws the jacks and sinks the frame face at the back of the needles to divide the loops and bring them to the needle heads, throwing the framework upwards and backwards, and leaving the thread in the needle-heads. He now presses down with the needle presser all the needle-beards, and brings the back loops to the needle-heads, moving the frame so as to bring the sinkers over the arch and be ready to form another set of loops. The set of movements first described for laying in the elastic thread must now be repeated and followed by the movements just described, and each set of movements worked alternately throughout the process of manufacturing the fabric or garment. *Patent abandoned.*

3108. J. Arbos. *Improvements in generating certain gases for obtaining motive power and in the apparatus employed therein.* Dated November 19, 1862.

This invention consists in a new gas engine, together with an apparatus for generating the gas, constituting one complete apparatus (as described with reference to the drawings), whereby motive power is created and transmitted; its characteristic feature is the production of a gaseous mixture composed of oxide of carbon, of hydrogen, of azote, and of a small proportion of carburet of hydrogen. This compound combined with air in proportions varying with its richness in carburet of hydrogen, and inflamed or exploded by an electric spark or by red-hot platinum wires, exerts inside a cylinder a pressure which becomes a motive power upon a piston therein, which power is transferred to the main shaft of the engine or apparatus to be transmitted or used as required. At the same time as the gaseous compound is generated steam is produced which may also be employed as a motive power, and may be used in a cylinder coupled with the gas engine. *Patent completed.*

3109. R. A. Brooman. *Improvements in tubular boilers, condensers, and superheaters.* Dated November 19, 1862.

This invention consists in the employment in boilers, condensers, and superheaters of helical instead of straight tubes. The tubes may have one or more turns in their length. The invention also consists in obtaining similar effects in straight tubes to those resulting from the employment of helical tubes by the fixing therein or thereon screw or twisted vanes. In boilers, however, in which the products of combustion pass inside the tubes, such vanes will not be applicable, because not being in contact with water they would be rapidly consumed. They apply, however, in condensers and superheaters, and may also be used in boilers with vertical tubes, round the outside of which the gases and products of combustion pass. *Patent completed.*

3110. G., C., W., and J. Kilner. *Improvements in means and apparatus for the manufacture of glass.* Dated November 19, 1862.

In the manufacture of glass the melting furnaces used are generally supplied with air from the "caves" or passages under the furnaces, and the fire-bars are covered with limestone to prevent in some degree the intense heat of the fires above corroding the bars. These improvements consist in keeping these bars cool by throwing jets of water upon them during the time of operating. For this purpose the water is conveyed through suitable pipes in the caves, and by pressure forced through perforations or nipples in these pipes in jets on to and between the bars, thus economizing the use of the fire-bars, dispensing with and saving the expense of the limestone, and producing a more intense heat in the furnace at a less cost of fuel by the vapour generated combining with the air of the atmosphere which passes through the furnace fires. *Patent completed.*

3111. J. B. Edmondson, J. Carson, and J. Blaylock. *Improvements in machinery for printing, numbering, and dating railway and other tickets.* Dated November 19, 1862.

The first part of this invention relates to those machines for which former letters patent were granted to Thomas Edmondson for printing and numbering railway tickets on the 19th March, 1850, No. 13,007. In these machines it has hitherto been customary to work the type-box and the numbering apparatus independently of each other, thus entailing two distinct operations of printing when the tickets had to be numbered at both ends. By these improvements tickets can be printed and numbered at both ends by one operation of printing, or one end only can be numbered or the numbers left out entirely, as may be found requisite. The second part of the invention relates to railway or other ticket-dating machines. In machines of this description it has been hitherto customary to supply ink to the types by means of a tape saturated with printing ink, such saturated tape passing between the face of the types and the tickets to be dated. By these improvements the tape is dispensed with, and the inking of the types is effected by means of an inking roller. The third part of the invention consists in using discs, in which slots or apertures are made for the purpose of inserting types, instead of using wheels or discs on which the dates are engraved as at present in use. *Patent completed.*

3112. R. Hardman. *Certain improvements in looms for weaving.* Dated November 19, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3113. G. A. Buchholz. *An improved mode of manufacturing semolina and flour, and apparatus to be employed in such manufactures.* Dated November 19, 1862.

The chief object of this invention is to obtain a larger per-centage of semolina, or of flour, from a given quantity of corn than is capable of being produced by the ordinary process of manufacture. To this end, the patentee first hulls the wheat intended to be converted into semolina in a novel construction of apparatus, the acting surfaces of which are formed of a peculiar arrangement of metal blades, which, when the apparatus is set in motion, give to the grain the friction requisite for removing the outer skin, or the greater portion thereof. When the grain has passed through this hulling machine, he separates the bran or hull therefrom by means of brushes, and afterwards submits the grain to the action of a novel construction of crushing roller mill, whereby a large portion will be reduced to semolina fit for the market. This he separates by means of sieves from those portions which still retain bran upon their surfaces, and the yet unbranned portions he submits to the action of mill stones, so set that they will impart only so much friction to the particles of crushed corn as will serve to destroy the adhesion of the bran thereto. This being effected, he next, by means of a dressing machine, separates the small portion of flour and semolina formed during the crushing and grinding processes, and by subjecting the semolina to blasts of air, he discharges the remaining bran therefrom. *Patent completed.*

3114. J. T. Hutchings. *Improvements in the construction of waterproof boot and shoe soles.* Dated November 20, 1862.

This invention consists in the application of leather to india-rubber or compound boot and shoe soles, which leather the inventor applies in a manner so as to form a border or edging to such soles. He selects soles of a size sufficiently small, so that, when the border or edging is attached, it shall be the required size; but, previous to such attachment, he destroys the uniform surface of the outer or top part of the sole, either by indenting, fluting, grooving, or perforating, which he does either by cutting, drilling, stamping, punching, or moulding. *Patent abandoned.*

3115. J. Jewsbury. *An improvement or improvements in machines for raising weights, which improvement or improvements may also be applied to lathes.* Dated November 20, 1862.

This invention consists in the application to machines for raising weights and to lathes of the mechanical arrangements hereinafter described, by which the motion communicated to a shaft or axis is reduced in speed and proportionately increased in force, in a simpler manner than by the mechanical arrangements ordinarily employed for that purpose. The patentee constructs a crab for raising weights as follows:—On an axis, turned by a winch or otherwise, an eccentric is fixed, the said eccentric carrying a pinion. The said pinion is loose on the eccentric, and square shoulders or pins on the said pinion engage in slots in an oscillating plate or arms. The said pinion has, therefore, no rotary motion. The said pinion is situated in, and engages with, a hollow-toothed wheel having one or more teeth more than the pinion. On each rotation of the axis carrying the pinon, the said pinion is carried round the hollow-toothed wheel, and causes the said toothed wheel to advance to the extent of one or more teeth. In order still further to increase the power of the machine, the arrangement described may be repeated—that is, the hollow-toothed wheel may carry an axis on the end of which is a second pinion, incapable, like the first, of rotary motion. The second pinion engages with a second hollow-toothed wheel, which carries a hollow axis working on the axis of the first toothed wheel. The said second toothed wheel advances to the extent of one or more teeth during one rotation of the first toothed wheel. The chain or rope by which the weight is to be lifted may be wound on the hollow axis of the second toothed wheel, or the said axis mary carry a pinion engaging with a rack. The application of the invention to pulleys for raising weights resembles, in all essential respects, its application to crabs already described. In applying the invention to a lathe, he makes an eccentric on the end of that part of the shaft carrying the driving pulleys, the said eccentric carrying a pinion incapable of rotation. The said pinion engages in a hollow-toothed wheel on the end of the shaft of the lathe head. The motion of the pulley shaft carries the pinion round the hollow-toothed wheel, and causes it and the lathe shaft to advance through the distance of one or more teeth on each rotation of the pulley shaft. The lathe shaft and pulley shaft may be coupled together and made to rotate at the same speed by throwing out of gear the oscillating plate or arms which engage with the shoulders or pins of the pinion, and connecting the two shafts together by a pin or otherwise. *Patent completed.*

3116. O. Stevens. *An improved brick-making machine.* (A communication.) Dated November 20, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3117. G. W. Oldham. *Improvements in preparing and dyeing silk waste, flax, hemp, Indian or China grass, or other similar or fibrous substances.* Dated November 20, 1862.

This invention consists, principally, in a peculiar method of preparing silk waste (or "husks" and "knubs"), flax, hemp, Indian or China grass, or other similar fibrous substances, for dyeing, whereby the patentee is enabled to dye the said materials either in black or colours, and sufficiently even in colour, previously to their being dressed or combed—that is to say, before being made into slivers, or before being mixed with wool or other fibrous material or materials—such fibrous substances having been hitherto invariably dyed after such operation. Secondly, this invention consists in dyeing such fibrous substances so prepared previously to their being dressed or combed—that is to say, before being made into slivers, or before being mixed with wool or other fibrous materials. *Patent completed.*

3118. F. Fletcher. *Improvements in the arrangement of a vessel or vessels for the compression of air as applicable to lift or force pumps.* Dated November 20, 1862.

In carrying out this invention, the patentee dispenses with the solid plank of wood, and substitutes in the place thereof a hollow box or frame of iron, or other suitable material, into which he inserts a suitable tube through a hole at the top, and on or against which box or frame he fixes the cylinder or barrel of the pump, and, if the situation require it, the handle or other apparatus necessary for working the same. This hollow box or frame of iron, or other suitable material, he makes into a vessel for the compression of air by inserting or attaching the delivery pipe thereto, by which arrangement a continuous flow of water from the delivery pipe is obtained while the pump is at work. The invention consists in using the above-named hollow box or frami for the purposes of a rest or support for the pump or pumps, and for a vessel in which to compress air. *Patent completed.*

3119. R. A. Brooman. *A method of, and apparatus for, indicating and recording the course of ships and vessels.* (A communication.) Dated November 20, 1862.

This invention consists in recording upon paper the actual course run by a ship by the combined agency of photography with natural or artificial light, the compass, and clockwork. The apparatus is called by the inventor a "Lozodrograph." In the binnacle, under the compass, clockwork is fitted for the purpose of unwinding paper, sensitized in any manner followed in sensitizing paper for the photographic process, from a roll, and of winding it on another roll. The rolls are placed on opposite sides of the binnacle, and the paper is drawn horizontally across and under the compass. A small object is placed upon the disc of the compass, say at the north pole, throwing down or projecting a very intense luminous point upon the sensitized paper. The effect produced is this—that, if the ship proceeds, for example, in a straight line from north to south, the luminous point will also trace on the paper a straight line from noth to south, and so on for all changes in the ship's course. Should the ship be compelled to turn round, the luminous point will trace an elliptical figure. The action is infallible; as the paper turns with the ship while the object remains stationary under the influence of the north pole. The speed at which the paper is made to travel being known, it becomes easy to ascertain exactly how long a ship has run ou such and such a tack. *Patent completed.*

3120. J. W. Child. *Improvements in means and apparatus for working wool and other fibres.* Dated November 20, 1862.

These improvements relate—1, To the use of glycerine or combinations thereof with oleaginous, fatty, or saponaceous matters, to facilitate the working of wool and other fibres in the various processes before weaving, either instead of oil, or in cases where the use of oil is, from various causes, objectionable. The improvements relate—2, When working wool by straightening or drawing the fibres thereof after they have been subjected to the combing process, to opening it by effecting partial separation or loosening of the fibres in a direction at right angles to the line of draught. For this purpose, the working teeth of the straightening or drawing apparatus employed have, in addition to their forward motion, motions at right angles thereto, and in opposite directions to each other. *Patent completed.*

3121. F. Leiler. *Improvements in motive power engines, and in apparatus for conveying and distributing motive power.* Dated November 20, 1862.

This invention relates to certain novel modes of applying compressed air, and to arrangements of machinery and apparatus for conveying and communicating motive power, to machinery more or less distant from the prime mover for raising and forcing water and other fluids, and for other useful purposes. The compressed air is not permitted, when thus employed, to escape after having once performed its work, as in air engines hitherto employed, but is enclosed or confined in the apparatus, and constantly used over again, and only such small portion of air as is lost by leakage, has to be replaced, and is, when employed, forced into the apparatus by means of a force pump. The greater the pressure of the air (consistent with safety) the more perfect is the action of the various apparatus. In carrying out the invention, the patentee makes use of compressed air of one uniform pressure, or he uses volumes or bodies of compressed air varying in pressure; he also uses compressed air in conjunction with water or other non-elastic fluids; and, lastly, he uses steam in conjunction with water and compressed air. The invention cannot be fully described without reference to the drawings. *Patent completed.*

3122. R. B. Seeley. *Improvements in inkstands.* Dated November 20, 1862.

For the purposes of this invention, in constructing an inkstand an ink vessel is used of the form of a nautilus shell, or other shell of the cephalopoda class, and the inventor makes such vessel of glass, china, or of other suitable material, and in some cases uses shells for the outer vessel. This vessel is mounted on axes, which are supported by and turn in bearings fixed on a suitable platform or surface. Into the opening or entrance of this shell-shaped vessel as large a dipping vessel or receptacle is introduced as the opening or entrance into the vessel will admit. Into this inner receptacle the ink is caused to flow, when the inkstand is about to be used, by simply moving the ink-vessel on its axis, so as to bring the open part of the vessel and the inner receptacle into a horizontal position, and the ink is caused to flow back into the interior of the shell-shaped vessel by a reverse motion of the vessel on its axis. The interior of the dipping vessel is lined with india rubber, or other suitable soft material, in order that the nibs of a pen may not be injured should they be dipped so deep into the interior or dipping vessel as to come in contact with the bottom thereof. In combination with the above construction of inkstands a frame is applied arranged to receive a piece of soft sponge, together with receptacles for a taper sealing-wax, instantaneous matches, and suitable friction or rubbing surface to ignite such matches. *Patent abandoned.*

3123. J. W. Hjerpe, W. Holmgren, and A. V. Sunstedt. *An improved composition or preparation of materials applicable for igniting matches.* Dated November 20, 1862.

This invention has for its object—1, to dispense with the use of phosphorus in the manufacture of matches, and also to prepare and apply the igniting ingredients in such a manner that matches cannot become accidentally ignited, and, in fact, cannot be ignited at all, except by being rubbed on a roughened surface especially prepared for the purpose. The improved composition consists mainly of chlorate of potash, bi-chromate of potash, to which may be added a metallic oxide, such as the oxides of iron, manganese, lead, or other metal, or a metallic salt. These ingredients are mixed and incorporated with glue, gum, or some adhesive preparations by grinding them up with the addition of a suitable quantity of pulverized glass, or other substance, to form a roughened surface that is sufficient to produce friction. *Patent completed.*

3124. W. Bottomley. *Improvements in machinery for stiffening woollen and other fabrics.* Dated November 21, 1862.

This machine is constructed of a width equal to the fabric to be stiffened. Across one end of the machine is fixed a perforated pipe, which is connected by another pipe to a cylinder of a pump of sufficient dimensions to contain the amount of paste or other stiffening liquid intended to be used. The cylinder of the pump is provided with a piston which may be worked backwards or forwards by means of a screw or rack connected with certain spur and bevel wheels; or it may be otherwise put in motion. The paste or other stiffening liquid is placed in the cylinder, and the end of the piece to be stiffened is carried under the perforated pipe, and as the machine is set in motion the piston presses the paste or other stiffening liquid in the cylinder through the connecting-pipe to the perforated pipe, and thence through the perforations in the perforated pipe, making the liquid exude in a uniform and steady shower, which falls on the cloth or fabric as it passes under the perforated pipe. The end of the cloth or fabric is then caused to pass between one or more pairs of pressing rollers in the machine, until nearly the whole length of the piece is sprinkled. It is preferred that the pressing rollers should be acted on by springs to cause the desired pressure. The two ends of the piece are tiod or fastened together, whilst the tail end has still to pass through between the pressing rollers, thus making the piece endless. The piece is passed several times continuously through the machine, until the stiffening matter is equalized in the cloth or fabric. The quantity of paste or other stiffening liquid to be applied to any given length of cloth or fabric can be exactly regulated by means of cog or spur wheels connected with the screw or rack, or other mechanism which communicates motion to the piston. *Patent completed.*

3125. W. Sinnock. *Improvements in the treatment and combination of fibrous and other materials, and in the arrangement of apparatus for manufacturing the same.* Dated November 21, 1862.

This invention consists in the treatment of hide offal and cuttings and shavings, and waste of manufactured leather, and in the combination of the animal tissue resulting therefrom, or in the combination of animal fibre (prepared by means well understood) with woollen or hair materials either spun, woven, or filled, or otherwise; or with vegetable fibre, half stuff or pulp, or by an admixture of the several materials mentioned in equal proportions, but which may be varied according to the subsequent use and application of such manufacture; and the treating or mixing the same with earthy or metallic chlorides, such as calcium, aluminium, tin, gums, resins, bituminous matters or substances, so that such compound materials may be either cast, moulded, felted, made, or compressed into suitable forms, such as sheets, slabs, blocks, or cylindrical rolls, which, when sufficiently solidified by the extension of all matters of solution, may be divided into separate or continuous sheets or webs of such compound fibrous materials. *Patent abandoned.*

3126. O. Hadfield and W. A. Attkins. *Improvements in compressing or dressing bricks and tiles.* Dated November 21, 1862.

This invention consists in the construction and employment of a revolving table or frame, upon or in which any convenient number of moulds, open at the top, and each fitted with rising bottom dies and pistons (actuated as after described), are placed, fixed, formed, or fitted, and a rising and falling main piston, actuated by a crank, and also working radially into and out of each succeeding travelling mould, passing respectively under the said piston as the table revolves. The travelling mould pistons are made in box form, open at the top to receive cushion dies; these pistons form the bottoms of the moulds in which they are accurately fitted, and are also caused to rise and fall therein more or less as required, and to operate by their upward pressure simultaneously with the downward pressure of the main piston working into and out of each mould as before described. The travelling mould pistons and bottom dies are actuated by two semicircular planes, fitted upon a bed plate under the revolving table, upon which inclines the said bottom dies and pistons are respectively supported and travel as the table revolves, and are thereby caused to rise and fall in the moulds. The sides of these moulds are made hollow, or in double case, to receive steam, hot water, or air for heating the same to prevent the necessity of lubrication. The revolving table and rising and falling pistons of the machine are actuated by suitable gearing driven by a steam engine or otherwise; and the bricks, tiles, clay, or other materials having been thereby subjected to the required compressing forces, and having received the desired form, are lifted out of the moulds by the continued rising of the bottom piston along the circular incline until it arrives at the highest point thereof, when the compressed articles are removed, and their place supplied by other materials. *Patent completed.*

3127. J. Townsend. *Improvements in damping and preserving vegetable substances, and vegetable and other textile materials and fabrics.* Dated November 21, 1862.

The patentee claims—1, The use of solutions of the compounds of chlorine with magnesium, calcium, and sodium, in conjunction or combination with the chloride or sulphate of zinc, or of tin, or with the chlorides or the sulphates of other metals, for preserving, or for damping and preserving, vegetable substances, and vegetable and other textile materials and fabrics, as described. 2, The using of solutions of sulphate of magnesia, in conjunction or combination with other sulphates of the metals, or of the alkalies, or with the chlorides of the metals, for preserving, or for damping and preserving, vegetable substances and vegetable and other textile materials and fabrics. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated Feb. 22, 1863.

502. W. E. Gedge, 11, Wellington-street, Strand. Improvements in the manufacture of hats. (A communication.)

Dated Feb. 27, 1863.

554. J. A. Coffey, 4, Providence-row, Finsbury, engineer. An improved method of, and apparatus for, controlling and facilitating locomotion whether on land or on water.

Dated April 2, 1863.

853. A. P. Price, 47, Lincoln's-inn-fields, chemist. Improvements in apparatus employed in the fusion, manufacture, production, and refining of metals.

Dated April 6, 1863.

867. W. E. Gedge, 11, Wellington-street, Strand. Improvements in aerial machines. (A communication.)

Dated April 24, 1863.

1027. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. A filtering apparatus for treating by pressure oils, syrups, and all sorts of liquids susceptible of filtering. (A communication.)

Dated May 7, 1863.

1143. G. Bower, St. Neot's, Huntingdon, gas engineer, and A. Dick, Alfred-street, City-road, chemist. Improvements in the purification of gas ordinarily used in illuminating, and in the reduction of ores and smelting of metals by means of such gas so purified.

Dated May 9, 1863.

1175. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in rotary engines. (A communication.)

Dated May 11, 1863.

1185. J. Shanks, Arbroath, machinist. Improvements in machinery for cutting or shearing the edges of grass or turf.

Dated May 15, 1863.

1225. R. T. Mallett, 11, Bridge-street, Westminster, civil engineer. Improvements in the construction of piers, walls, and other similar stuctures, and of landing stages, and in the constructions therewith or attachments thereto.

Dated May 16, 1863.

1231. R. Talbot, Strand-on-the-Green, Chiswick. A folding rudder for steering barges in the river Thames or coastwise.

1237. T. C. Stretton, Old Basford, lacedresser. Improvements in machinery or apparatus employed in the dressing of lace or other fabrics.

Dated May 19, 1863.

1251. J. H. Johnson. 47, Lincoln's-inn-fields, gentleman. Improvements in breech-loading firearms. (A communication.)

Dated May 21, 1863.

1274. E. T. Hughes, 123, Chancery-lane. Improvements in breech-loading firearms and in cartridges connected with the same. (A communication.)

Dated May 23, 1863.

1301. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in indicating the position of trains upon railways, and in apparatus employed therein. (A communication.)

1304. F. Kingsbury, Cecil-street, professor of singing. Improvements in the construction of orchestras.

Dated May 25, 1863.

1308. G. Howell, Old Kent-road, stationer. A new double-action self-feeding, stamping, and printing machine.

Dated May 29, 1863.

1350. W. Loeder, New Broad-street, City, merchant. Improvements in rails for railways. (A communication.)

1352. G. H. Pierce, Plymouth, gentleman. Improved apparatus for heating buildings by means of hot water.

1354. W. Green, Margaret's-place, Old Ford-road. Improvements in the means or method of producing black colouring matters or pigments.

1356. F. Patureau, Paris, manufacturer. Improvements in the manufacture of cardboard or paper boxes or receptacles.

Dated May 30, 1863.

1351. E. P. Mosman, Enfield Highway, engineer. Improvements in obtaining and applying motive power.

1360. V. Baker, Lieutenant-Colonel in Her Majesty's 10th Regiment of Hussars, Dublin. Improvements in ordnance.

1362. W. Clark, 53, Chancery-lane, engineer. Improvements in the manufacture of manure. (A communication.)

Dated June 1, 1863.

1368. J. Davey, Crafthole, Cornwall, agricultural implement manufacturer. Improvements in horse-rakes.

1370. C. Belcher, Little Coxwell, Berks, farmer. Improvements in cutting and transplanting turf, and in apparatus to be employed therein, which apparatus is also applicable to the extraction of weeds, and to the planting of seeds, roots, sets, or plants.

Dated June 2, 1863.

1372. J. Mellard, Rugeley, Staffordshire, agricultural implement manufacturer. Improvements in double moulding or ridging ploughs.

1374. J. H. Brierley, Beech-hill Mills, Halifax. The application of leather in the manufacture of gentlemen's scarfs and ties.

1375. D. Wilson, Wandsworth-common, and E. A. Cowper, 35a, Great George-street, Westminster. Improvements in presses.

1378. T. Page, Adelphi-terrace, civil engineer. Improvements in shoeing horses.

1382. T. Agnew, jun., Manchester, publisher. Certain improvements in apparatus for coating or covering moulded or other surfaces with certain composition or material.

Dated June 3, 1863.

1386. T. Claridge, Bilston, manufacturer. An improvement or improvements in the manufacture of spur wheels used in the construction of mill and forge gearing, and for other like purposes.

1390. J. J. McComb, Liverpool, gentleman. Improvements in the construction of presses for forming bales of cotton and other materials, and in the construction of fastenings for and means of applying bands to such bales. (Partly a communication.)

1392. J. Maurice, 3, Langham-place, Regent-street, dentist. Improvements in rulers and instruments for ruling and in the mode of constructing them.

Dated June 4, 1863.

1394. H. Rigby, Salford, engineer. Improvements in steam boilers and furnaces for the consumption of smoke.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated June 8, 1863.

1418. G. W. E. Friedrich, 14, Shap-street, Kingsland-road. Ink.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, June 16, 1863.

299. W. Clark. Armour-plated and other ships.

309. G. Harton. Wood paving.

312. T. Bradford. Washing, wringing, and mangling clothes or other textile fabrics.

318. W. T. Weston. Spring catch.

319. B. Russ. Iron ships or vessels.

335. G. Stevens. Effecting a regular supply of air or aeriform fluids for various purposes.

339. J. Price. Signal lanterns.

342. J. Cameron. Manufacture of iron and alloys of iron.

346. W. F. Cooper. Distilling apparatus.

351. M. Hackforth. Shades or reflectors.

352. G. Redrup. Cutting of shives, bungs, corks, spiles, and vent and other pegs.

361. J. Crossby and J. B. Smith. Carding fibrous substances.

363. R. Burley. Hammers, mallets, picks, mattocks, and similar tools.

368. A. Corneau. Hot-air stove.

371. J. Duckworth. Manufacture of paper.

375. W. Symington. Weaving.

378. H. Wycherley. Applying wings or dirt screens over the wheels of carriages.

387. W. E. Gedge. Promoting the comfort of persons at sea. (A communication.)

389. J. F. Spencer. Steam engines.

390. J. Robertson. Printing woven fabrics.

400. W. C. Paul and A. T. Shore. Spring mattresses.

403. W. Baylis and T. H. Hopwood. Tongs or forceps for grasping articles out of reach of the hand.

416. C. D. Abel. Omnibus. (A communication.)

464. C. W. Siemens. Telegraph line-wires.

480. H. Mackinder. Separating potatoes into different sizes.

789. G. Cowdery. Making bricks.

927. R. Leggett and R. Gittus. Cutting chaff and other agricultural produce.

1030. S. Harrison. Type.

1091. E. G. Brewer. Welding and rolling metals. (A communication.

1167. W. Boaler. Dryer fabric for paper making.

1185. J. Shanks. Cutting or shearing the edges of grass or turf.

1194. H. L. Emery. Ginning cotton. (A communication.)

1251. J. H. Johnson. Breech-loading firearms. (A communication.)

1313. H. B. Girard. Heating of every industrial and private apparatus by means of the oxygen and hydrogen gases combined and obtained from the decomposition of water.

1322. J. Munro and R. Scott. Boring, mining, and excavating or cutting in motive power engines, and in pressure gauges.

1382. T. Agnew, jun. Coating moulded or other surfaces with certain composition or material.

1418. G. W. E. Friederich. Ink.

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed June 12, 1863.

ARMOUR AND BACKING.

Our readers are far too well acquainted with the results of the experiments conducted by the Armour-plate Committee, to require their recapitulation at our hands. They have demonstrated, in our opinion, plainly enough, that the result most to be dreaded from the shot of an enemy is the fracture of the bolts which serve to attach the armour to the ship's side. Little or no difficulty is now experienced in forming plates which will effectually prevent, for a time at least, the passage through them of any shot that has ever been propelled from a gun. Our great iron companies could supply armour 12 in. thick, were it expedient to use it; but the weight of such plates, putting their cost aside, is quite sufficient to prevent their adoption for ships much short of 10,000 tons burthen. They are, perhaps, in the present state of the gun question, unnecessary; 4 in. or 5 in. of good iron possesses an amount of resistance which is, for anything we can see to the contrary, sufficient to meet all the demands likely to be made on its endurance in practical warfare—that is to say, it is able, as a general rule, to prevent the entrance of shot into the interior of the hull, without the employment of exceptional ordnance, such as no nation with whom we are likely to go to war possess as yet, or at a range so close that the conflict would quickly become a question, not of shot and plates, but of cutlasses and revolvers.

All the experiments, then, hitherto undertaken, show plainly that it is not so much the penetration of individual plates which is to be feared, as the disorganization of the entire portion of the ship's side fired at. Thus, we find that, in the case of the best targets produced, although the shot failed to penetrate, they were able to destroy, and it required but a prolongation of the process to cause the total destruction of the objects fired at, which suffered so severely from the effect of even a few heavy shot fired at short range that they almost fell asunder. Iron-plated ships are, in fact, exposed to precisely the same evils as a stone fort. Shot cannot penetrate a wall 8 ft. or 10 ft. thick; but it can, if the firing is continued, cause the wall to crumble into a ruinous breach, however strongly it may be built, cramped, and bound together; and were the "Warrior" or "Royal Oak" exposed to continuous fire for twenty-four hours, at a moderate range, although it is extremely probable that single shot would not penetrate to their hulls while their armour remained on their sides, it is not difficult to see that after a little time this would fall away piecemeal by the breakage of the bolts, and the destruction of the side of the hull would follow as a matter of course.

The question is, in our opinion, not so much what is the best kind of plates, or the best thickness for them—that we regard as sufficiently settled for the present—but what is the best mode of fixing and backing them? Not so much on the resisting powers of the plates as on the strength of the bolts, does the invulnerability of the ship rest. The strain on the bolts depends almost wholly on the nature of the backing employed in combination with them. In this lies the gist of the question; for it is of little avail to use plates perfect in themselves if they are to fall off in the hour of danger.

The breakage of armour bolts results from a very simple cause; when a slab of iron, thick or thin, resting on a yielding support, is struck with sufficient force any place near the centre, the edges turn up and the plate becomes slightly convex. Thus, an armour plate, supported by an elastic backing, no longer remains flat when struck by a shot, even if the force of the blow is not sufficient to cause a permanent bending or deflexion, by overcoming the limit of elasticity of the plate; still that very elasticity must permit a certain rising of its edges from the backing, quite enough to tend powerfully to the fracture of any bolts holding them down; the region where the shot strikes is driven in on the backing; the *vis inertia* of the rest of the plate resists this; it is slightly, though not permanently, bent by the impact of each shot, as a consequence; and the prevention of this bending is the real purpose which backing should fulfil. Until that is accomplished, a strain must be thrown on the bolts which can hardly fail to occasion their facture. Were the entire surface of a plate struck at once, elastic backing would be practically perfect, as it would admit of sufficient motion to absorb the force of the shot; this is not the case, and in consequence rigid support becomes a necessity.

Although it is more than doubtful that we shall ever secure anything of the kind, in the fullest sense, still we may approach sufficiently near to it to reduce the strain on the bolts so much that it easily comes within their powers of resistance; for, even if we suppose the backing not so rigid as to wholly prevent the depression of that part of the plate which receives the shot, still it may yield so slightly that a strain, very moderate indeed, is put on the bolts. The rigidity of the one and the strength of the other would seem to be capable of being nicely proportioned; increased elasticity demanding a stronger bolt, *vice versâ*. A plate of iron, 4½ in. thick, fitted with mathematical exactness to the surface of a block of steel weighing, say 100 tons, might, we feel little doubt, be struck over and over again by shot without being penetrated or rising at the edges; the entire force of the shot would be to a great degree transmitted to the steel block; and even were the plate not very accurately fitted to it, still its support would be so great that little strain would be thrown on the bolts which affixed it.

The question then narrows itself into the construction of a backing rigid enough to prevent such a motion of the central portions of the plate, as will cause the edges to rise with sufficient force to break the holding on bolts; no amount of wood backing will ever effect this without such an increase in their diameter as would effectually preclude their use. Iron can alone supply the support armour requires. Combine it with wood, if need be, but let that act merely as an auxiliary—never, under any circumstances, as a principal. The proper form under which to apply the stubborn metal as backing is a problem for the naval architect to solve—whether in separate girders or plates fixed on the edge, outside of, and distinct from the hull, or in the shape of a great increase in the size of the ribs proper of the ship, just under the armour, time and experiment alone can decide; but, certainly, no consideration of a little extra weight should influence the decision. Of what avail is it to clothe a ship with 300 or 400 tons of armour, which hampers all her movements, and yet may be found useless in the day of battle? How much better to supply, if needful, 200 tons more of backing, if we can by that means secure her practical invulnerability; little difficulty would be experienced in saving the extra weight in the engines and internal fittings of the ship with positive advantage. We trust we shall not again hear the relative weights of targets used as a means of comparison when considering their applicability to the purpose in view, while so much weight exists inboard which could so well be spared.

FIXED RULES AND THE STEAM-ENGINE.

There are few subjects on which more books have been written than the construction of the steam-engine. The beauty of the scientific truths involved; the grace, so to speak, displayed in the movements of the finished machine; the fact of its being, to a great extent, the basis of our whole social system, the source, not alone of our wealth, but of our luxuries, the spirit ministering to all our necessities, could not fail to constitute it an attractive object to scientific authors. By some it has been handled poetically; by some, philosophically, scientifically, mathematically, popularly; by very few, sensibly; and in spite of the mass of printed matter which bears on the subject, considerable difficulty is experienced in gathering any really useful information from existing books. We need never be in doubt, it is true, on any matter connected with it, provided we are content to take certain guides, and trusting ourselves wholly in their hands, progress towards the results to which they would lead us; but if our minds are unfortunately so constituted that we cannot quietly submit to accept one guide, without inquiring into the merits of others, we at once find ourselves adrift, for each proposes to lead us to the same goal by roads differing widely in direction and smoothness. Such, perhaps, will always be the case, and we regret it, for the fact has proved more injurious to the steam-engine, and a more powerful cause of delay to its progress, than ignorance or direct prejudice on the part of the constructive engineer ever could have been.

The assertion that the steam-engine is, in one sense, the most imperfect source of power we possess, may be startling; little reflection is requisite to prove it true. We can hardly be said to possess any other mechanical source of motion, save falling water. Animal strength and the force of the winds may prove very useful under certain limitations, but they play a very inferior part in our manufacturing economy as compared with water. Both from the antiquity of the use of this power, and from the extreme simplicity and invariable character of the laws on which its energies depend, everything relating to it has become thoroughly well known; and very little difficulty is experienced in constructing a water-wheel which will give forth a useful effect or modulus, equal to 70 or 75 per cent. of the theoretical useful effect due to the fall of which we avail ourselves.

In the steam-engine, on the contrary, we find a machine whose entire success depends on the accurate acquaintance of the engineer, not only with laws scarcely yet well defined, but also with the exact applicability of each or any of them to certain cases and circumstances, which must always be exceptional, and vary with different engines. The question of fixed rules for steam-engine construction becomes as a consequence complicated to the last degree, and presents difficulties sufficient, in our opinion, to have long since banished them from anything pretending to be a sensible book. The difficulty of practically carrying out theory; our comparative ignorance of what theory really says truthfully on the matter; the exigencies of diverse situations into which the steam-engine has to be fitted, as travellers were on the bed of Procrustes—have all operated very effectually in preventing its average of useful effect, approaching even distantly to the practical perfection of the water-wheel or turbine. Instead of 70 or 80 per cent., we realize about 30 per cent. of the power due to the combustion of the coal consumed; in other words, we burn three times as much coal as we ought.

But one thing can set this great evil right; for it is a great evil, regard it as we may. Teach our engineers an accurate knowledge of the principles involved; but, for the sake of progress, banish for ever the collections of arbitrary and dogmatical rules with which the shelves of our libraries, and our brains are equally burdened. We do not mean to assert for a moment that certain rules are not useful; nay, we will go so far as to admit, that to a certain limited extent they may be absolutely indispensable; but this can only be the case when they are made use of for the purpose of avoiding grave errors, not as being in themselves guides to success. Their proper function is to point out the course of construction which is positively wrong, not that which is absolutely right. Their use once narrowed to this, their legitimate province, they become serviceable; in the present state of things, they are not only worthless, but to the last degree mischievous.

The steam-engine differs from nearly all other machines, in that its success depends, not on one, but a multitude of principles, each to a certain extent demanding the observance of certain rules of construction, most of which are incompatible one with the other when the various principles are combined to form a whole. Not so, perhaps, provided we had infinite space in which to erect our engines, but this not being the case, our assertion is in the main correct. Thus, a heating surface, as compared with grate surface, three times what it is now, would be very advantageous provided it were attainable on board our steam boats, but unfortunately it is not, because the principles which guide us in the construction of the marine boiler must submit to the influence of those which regulate the construction of a ship. To go further, apart from what we may term external agencies, we find internal features and working necessities, which frequently lead to wide deviations from correct principles, which may clash in their application, to such an extent that each must yield to the rest. We might fill volumes with instances of the kind, but they are so obvious as scarcely to need illustration at our hands. We will point out one. On correct principles of water-heating, we should deprive the waste gases from a furnace of all excess of temperature above that of the water within the boiler. So far so good; but, on looking further, we discover that to ensure rapid combustion, when that is nesessary, the gases must possess a very much higher temperature in order that they may ascend the stack with sufficient velocity.

In short, the more we go into the question, the greater we find the difficulty of applying any fixed or arbitrary rules to the steam-engine, the only *machine* which is commonly employed to supply motive power. The water-wheel and the wind-mill are *instruments* depending for their success, each on a simple principle. The steam-engine derives all its energy from many different principles, which permit not only considerable latitude individually in their application, but positively cannot be employed in combination, without, to a certain extent, sacrificing much that renders each most perfect. We ask then, how can fixed rules properly apply to a machine complicated in its form and a hundred times more complex in its principles? Were it possible to draw up a code of laws which would be applicable to every varying circumstance, different form, and varying purpose under which it is found, or to which it is applied, they would form a book so gigantic that it would be valueless; no one could read it, none comprehend it. Even were such a book compiled, and granted that it was absolutely perfect now in 1863, who could say with certainty that it would be equally correct in 1873? The last ten years have ushered in wonderful changes, and we feel little doubt that the coming ten years will produce results equally important.

The engine of James Watt bears little or no resemblance to the engine of the present day. His was colossal, magnificent, mighty in its appearance of power. The tardy giant certainly conferred blessings on the manufacturing world, such as no motive power which had gone before had ever done. But this giant was costly to keep, slow in his movements, and his size and beauty formed but a useless pageant. The condenser came to be looked on as the most essential part of the engine—the source of all its power. We, half-a-century later, have learned that it is but a useful adjunct, a means of realizing the last fraction of economy, but not in any way necessary or indispensable to the development of power from the combustion of fuel. But all the rules at present employed by steam-engine builders date back, with scarce an exception, to the reign of Watt, and are, as far as possible, forced into modern practice, whether applicable or not. As well might we retain the old hemp-packed piston, as the exact area of grate, or speed of piston, which the engineers of Watt's day gave us.

We may certainly apply empirical rules to the construction of a boiler, the speed of a piston, the height of a stack, &c.; but, *cui bono?* A different description of coals may render our boiler next to useless; the speed of piston adjudged to us may entail heavy multiple gear — a difficult situation may render expedient the employment of an engine constructed apart from all such rules. Of what avail, then, is it to print and publish, day after day, dogmas which can be of no general value, because they are not capable of general application? Why fix the speed of a piston at 300 feet per minute, when we find it do its duty equally well at 100 feet and 1,100 feet per minute? Why fix positively the area of a grate, when a little difference in the state of the air, in the quality of the coals, in the skill of the fireman, can alter the results obtained? Let our engineers rise above such narrow dogmatism; let them handle the subject liberally; let them study as carefully as they will the scientific truths involved in the working of every separate part of the machine they propose to construct; let them display their talents in the combination of these different parts, guided by an accurate and well-trained perception of that course of construction most suitable to the circumstances in which they have to act, not blindly following rules which alter not, like the laws of the Medes and Persians.

FRICTION.

There is a no more striking exemplification of the proverbial difficulty of mankind in arriving at truth, than that afforded by the apparently futile attempts of the physicist to explain the causes of daily and familiar phenomena. The answer to an inquiry as to what is Friction? appears simple enough; but, nevertheless, although few questions in natural philosophy have attracted more attention from the most powerful minds, the results have been scarcely in proportion to the labour that has attended these investigations. The first recorded experiments on friction were those made by Aumontons, in 1699. Then follow those of De la Hire, Parent, Leibnitz, Da Camus, Leupold, Sturm, Bulffinger, Desaguiliers, Muschenbroeck, Bossut, Ferguson, Dr. Vince, Coulomb, George Rennie, and Morin. The first observations on friction thus date more than a century and a-half ago; but not merely have we no generally received hypothesis that would completely account for the phenomena of friction, but the numerous experiments that have been made to clear up the question have only afforded us certain approximative values, often contradictory to each other, and as often only partially agreeing with practical experience.

The fundamental laws upon which engineers at present base their calculations as to friction, were determined about thirty years ago by the French *savant*, the then Captain, and now General Morin. According to Morin, the co-efficient of friction is independent of extent of surface and of velocity, and is in proportion to the pressure only. According to some fresh experiments lately made by M. Bochet, and recorded in the Memoirs of the Paris Academy of Sciences, friction diminishes with the velocity, while it varies with the surface rubbed—conclusions directly opposite to those of Morin, which have nevertheless afforded the data upon which engineers have relied for the last 30 years. We may here remind our readers that Ferguson also found that friction varied with the speed. This occurrence, however, is but a repetition of the preceding history of experiments in friction; the results of the experiments of Morin contradicted those of Coulomb in several ways, while the co-efficients and general results of Coulomb himself greatly differed from those of his many predecessors in this department of experimental science.

We hope to return to this important subject; but, in the mean time, we will allude to the various hypotheses that have attempted to account for the real nature of friction.

Most of these different theories have been collected together in an excellent treatise on friction, written by Herr Brix, of Berlin, and published some years ago in the "Verhandlungen des Vereins zur Befoerderung des Gewerbfleisses in Preussen."

As is well known, the surface of every substance in nature, however apparently smooth and hard, when examined under a magnifying glass, is found to consist of a series of little prominences and concavities—the ultimate particles of all bodies being always provided with interstitial spaces. The most generally received and popular explanation of friction is thus founded on the supposition that the prominences of each one of two sliding surfaces grip or catch into each other's concavities. An exaggerated picture of this would be given by imagining two toothed racks fitting into each other. When motion takes place, the asperities must either be bent and torn away from the surfaces of one or both of the two substances, or one of the two bodies must be continually lifted out of the inequalities of the other. This more especially applies to the sliding friction that takes place between two sliding surfaces. In rolling friction, as that of a ball or cylinder, the prominences are continually fitting into fresh concavities. The friction between an axle journal and its bearing is of a composite kind—between sliding and rolling friction. The theory deduced by Coulomb from his experimental researches is similar to the above, but of a more complete and detailed character. He supposes that the surfaces of woods, for instance, are covered with small elastic and pliable threads or fibres, which stick out like hairs on a brush, and can be bent in any direction; the surfaces of metals consist of angular or spherical inequalities, which, being hard and unbending, never change their form, whatever pressure may be applied. Starting from these data, Coulomb explains the peculiarities that take place when wood is rubbed on wood, metal on metal, and wood on metal. When wood is brought into contact with wood, the fibres of the one surface sink into those of the other, just as when the hairy sides of two brushes are pressed together, and this resistance against motion increases with the depth that the particles are sunk into each other. Metals, which are not covered with flexible fibres, but rather with hard unbending prominences and asperities, are impeded in their motion by these asperities interlocking with each other. The depth to which any of the substances will interlock with each, will be increased if they are left in contact for any amount of time. We have thus the explanation that the friction at starting, or of quiescence, is greater than when the surfaces are once brought into motion.

The effects of oil or grease in diminishing friction have been ascribed by Muschenbroeck to the fact that oil prevents the prominences on the surface from being broken off; as it consists of small globules which fill up the interstices, the elevations of the two surfaces are prevented from reciprocally grippihg into each other. The globular form of the particles of oil, being easily moveable, also facilitates the movement of the two surfaces. This last idea has been carried still further by the Abbé Rollet, who assimilates the lubricating power of oils to the action of rollers when placed under a heavy weight to move it along.

The celebrated John Leslie, however, in his work "On the Nature and Propagation of Heat," accounted for friction in a somewhat different manner. His theory, although remarkable for its ingenuity, does not seem to have attracted the attention it really appears to deserve. He rejects the explanation of friction upon the principle of the inclined plane; and that friction is produced from the effort required to make the weight move over successive series of eminences. "The mass which is drawn along is not continually ascending; it must alternately rise and fall; for each superficial prominence will have a corresponding cavity; and since the boundary of contact is supposed to be horizontal, the total elevations will be equalled by their collateral depressions. The force given out in lifting the weight up, is returned in letting it down again; and these opposite effects will thus neutralize each other." Adhesion appears still less capable, continues Leslie, to explain the origin of friction. As adhesion must be regarded as a force acting perpendicularly on the frictional surfaces of the solids, such a force can have evidently no effect in either quickening or impeding the motion along these surfaces. In his own words:—"Friction consists in the force expended to raise continually the surface of pressure by an oblique action. The upper surface travels over a perpetual system of inclined planes; *but that system is ever changing, with alternate inversion*. In this act, *the incumbent weight makes incessant yet unavailing efforts to ascend*; for the moment it has gained the summits of the superficial prominences, these sink down beneath it, and the adjoining cavities start up into elevations presenting a new series of obstacles which are again to be surmounted; and thus the labours of Sisyphus are realized in the phenomena of friction."

Not one of these theories may be said to properly account for the fact that friction in some cases will even exceed the weight with which the bodies are pressed together; and the numerous but unsuccessful attempts to arrive experimentally at definite laws, seem to point to something inherently defective in the means employed to approach determinate results. There is no doubt that friction is really a very complex phenomenon; as was remarked by Oersted, "There are many phenomena belonging to friction which are very far from being sufficiently explained." It is extremely probable that the comparatively new theories of thermal dynamics may shed some light upon the matter. Friction is one of the most powerful means of converting mechanical power into heat or electricity. Heat is always produced whenever friction is overcome, and the amount produced is the measure of the force expended in overcoming the friction. To neglect these transformations of power, would evidently often vitiate the results of the experimenter on friction. It has been noticed during these experiments, that with metals friction is increased by the temperature being raised; and, with woods, that it is increased when the material is damp. Nothing more definite than this general law has been as yet ascertained.

THE MANUFACTURE OF ARMOUR PLATES.

The history of the arts of peace affords many instances of their indirect advancement and extension through a parallel progress of the arts of war. Many examples of this fact could be cited. Confining ourselves to the history of the iron manufacture, we will merely recall to our readers that the first iron-castings in England consisted in some cannon for Henry VIII., and, coming to more modern times, that Mr. Bessemer made his first experiments in casting steel with a view of obtaining a good metal for heavy ordnance. Wars and rumours of wars have always acted as stimuli to invention; and the immense interests involved in the success or failure of a conflict of nations, have often directed the whole resources of a country towards the overcoming of a physical obstacle. The unlimited capital and resources, the complete organization of a Government, are directed into channels that, in times of peace, would have to be filled by the limited exertions of a few private individuals.

The youngest mechanic can remember the time when the production of large masses of wrought iron was a very difficult and uncertain process; while he can also recall to mind the failure of Mr. Nasmyth, the steam-smith *par excellence*, when attempting to forge a heavy piece of ordnance. The most inexperienced and unimaginative mind can also perceive the immense stride, the complete revolution, that would result to engineering if we could only obtain solid wrought iron for the many structures we are now compelled to build up out of separate parts. We are still very far from the goal; but everything tends to show us that in a few years we shall attain an immensely increased command over the production of wrought iron in large pieces.

That the large iron slabs now in demand for armour-plated ships will continue to be required, is indeed doubted by many, and with good reason. The almost unlimited dynamic force of gunpowder, when well employed, will always exceed the statical powers of cohesion in a mass of iron; and the narrow limits of weight that must characterize a floating and moveable structure, confine us in the amount of molecular power we can use as a defence against the penetrative impulse of a heavy and quickly-moving projectile. However that may be, the great attention given of late years to the production of a material for resisting the tremendous force stored up in gunpowder—whether directly exerted as in the chamber of a gun, or indirectly as through a projectile—will greatly advance the peaceful art of the civil engineer.

Up to the present time, the rolling mills of the Atlas Works, Sheffield, seem to have produced the largest armour plates, as was well witnessed in the iron slab weighing more than 20 tons, being 19 ft. long, 3 ft. 9 in. broad, and 12 in. in thickness, lately rolled out in the presence of the Lords of the Admiralty on the 9th of April last. A very glowing and flourishing account of the operation appeared in the *Times*, and none of the natural doubts engineers might have felt were expressed as to the homogeneous character of the product. This plate, though larger, was of the same description as the famous armour plate from the Atlas Works in the late Exhibition, 22 ft. long and 4 ft. wide, and which was manufactured in the following manner:—The puddled bars were rolled into plates 1 in. thick, 12 in. broad, and 30 in. long, and five or six of these were then made into a pile and then rolled into the shape of a plate, 4 ft. long by 4 ft. broad. Five or six of these were again taken to form a plate 8 ft. long, 4½ ft. broad, and 2½ in. thick, the whole weighing about a ton and a-half. Four of these plates, with their edges trued up, are laid one upon the other in the furnace, and the whole is then rolled out in a mill with a backward-and-forward motion.

Rolled plates are, of course, cheaper to make than forged plates; but it is very questionable whether the joints between the plates are properly welded. The lines at the joints can be seen very distinctly at the edges of the plate. It is impossible for the men to brush away the scale that naturally forms itself on the inside surfaces, while the plates are lying in the furnace. As was well observed by Mr. Nasmyth, in allusion to the vitreous oxide of iron:—"So long as any portion of this adhesive viscid substance is permitted to exist and interpose itself between the surfaces we desire to unite by welding, no sound or trustworthy junction can take place; and where it has made a lodgment, no after-heating or hammering, be it ever so severe, will cause its thorough expulsion." As in a rolled plate, the fibres lie in the direction of the length only, these rolled armour plates will be very tough and strong in this direction. Across the fibres, however, these plates will be very weak. The piles of Mr. Brown's plates are said to be made up out of Swedish iron. According to Mr. Fairbairn, this is not the best iron for armour plates:—"It is not the iron which opposes the greatest resistance to a tensile strain, or to compression, that is most effective to resist impact. The presence of a small proportion of carbon causes brittleness; and toughness, combined with tenacity, are the qualities required."

The Thames Ironworks Company manufacture armour plates entirely forged under the steam-hammer. Faggots are built up out of one to one and a-half hundredweight of scrap iron, and three or four of these faggots are welded into a flat piece by means of a few blows from the hammer. The forging is completed by again bringing the flat piece to a welding heat, and then giving it a taper or bevel under the hammer. The whole armour plate is then gradually brought together, from similar separate wedge-like pieces, by welding the tapered sides together. The last operation consists in the plates being forged, at a moderate heat, to the required thickness, by means of 10 to 20-ton steam-hammers, with a fall of from 8 ft. to 12 ft. Hammers of from 2½ to 5 tons are powerful enough for the previous operations.

At Codnor-park Works, in Derbyshire, armour plates are made by a combined process of both forging and rolling. Two rolled plates are laid one above another, and are welded under the hammer to the required dimensions. This process appears very practical, and likely to make a good job; but it involves the drawback of a large surface of weld, and the consequent uncertainty of getting a good joint, more especially in the centre of the plates.

Up to the present, the process employed by Mr. Brown, of Sheffield, appears to be the most successful, and to have produced the largest plates. Size is of importance, as the joints in an armour-plated ship are like the chinks in the armour of an ancient knight. These rolled plates are probably of a more homogeneous character, at least in the direction of their length, than those produced by faggotting up a number of wedges, to be afterwards forged together under the hammer. The pressure of the rolls is unattended with impact, and is uniformly applied to every part of the plate in succession. In each successive passage through the diminishing apertures between the rolls, the pressure increases in an inverse ratio to the size of cross section of the plate. That the obscure phenomenon of crystallization is sometimes induced in forgings while under the hammer, is undoubted, although an explanation of the fact may not be readily forthcoming. Mr. Clay, of the Mersey Forge, Liverpool, who has certainly produced some of the largest and finest forgings that were ever turned out, appears to hold a contrary opinion to the above. He writes:—"A great deal has been said and written with reference to a supposed deterioration, or, as it has been called, crystallization of iron when heated into large masses, from long-continued and frequent heatings; it has also been asserted that the iron while lying in the furnace, is continually attracting carbon from the grate, until, in the course of time, it becomes carburetted, that is, re-converted into pig-iron." For a large forging, parts of which are cold, the vibrations communicated by the hammer are said by some to be the main cause of the crystallization of iron. In order to test the truth of the assertion that iron was deteriorated by the causes he had cited, Mr. Clay took "a small knob or corner . . . . from a large forging which had been overheated or burnt; it broke off with a *large flaky appearance*, very similar to some descriptions of lead ore. This was pronounced to be very similar in its nature to cast iron, and in the so-called crystallized state. Proceeding to the smith's department, the iron was heated in the fire, and drawn down to about three times its original length. It worked well under the hammer, and when broken again in the usual way, was as beautifully fibrous as the iron from which it was originally made." It is surprising that such a practical metallurgist as Mr. Clay should have forgotten the fact that the pieces of iron forming the faggot are almost always *separately stronger* than when worked up into a large forging. If, instead of taking a small piece off his large mass, and *again* working it up, he had cut away a piece of such a size that it could at once have been tested for itself, the result would have been very different. This was actually done in 1843 by a Committee of the Franklin Institute. They found that original bars from a faggot, the strength of which was represented by 46, had their tenacity diminished to 38 in the forging, while it was recovered by the piece cut out being again worked up. It may be remarked that the crystallization of iron is also furthered by its being in a highly heated state.

The welds are, however, the weakest parts in these massive forgings. There is little other security against the presence of a false weld than that afforded by the presumed skill of the workman.

It is evidently a nautical question as to the limit of weight of the iron sides of our seagoing ships; but it is a manufacturing question as to the power of resistance that can be imparted to a plate of given thickness. As Mr. Grantham observes, in his work on "Iron Ship Building," in reference to ordinary ships' plates:—"The angle and the rivet iron are subjected in using them to the action of the fire and the hammer, and if they are of inferior quality will show it; but the *plates* are not much tried in working, and their quality escapes observation."

TRIAL TRIP OF THE LONDON AND MEDITERRANEAN STEAM NAVIGATION COMPANY'S STEAM SHIP "ITALIA."

We feel much pleasure in placing the following particulars of this vessel and her engines before our readers, because we are fully impressed with the value of any practical results which can tend to dispel the crowd of prejudice which proves such a powerful obstacle to the introduction of a lighter class of marine machinery. None of the arrangements may, perhaps, be very novel. Surface condensation is not new, neither is expansion nor superheating; valve gearing presents every possible variety of arrangement; many cylinders have been used ere now to drive one crank shaft; but the successful combination of these different elements, in a manner which will bear the trial of practical experience, is novel, and Messrs. Maudslay and Field deserve high praise not only for the success which has attended their exertions, but for the enterprise which has led them, without seeking after novelties merely because they were such, to adopt every invention which their experience led them to regard as likely to conduce to the securing of a good result.

We believe that Messrs. Maudslay usher in improvements which will lead to the regeneration of the marine engine; and we trust that ere long the machinery of a steam ship and the fuel necessary to supply its vitality, will cease to be a burden absorbing all her energies in their mere conveyance. The success of the "Italia," like that of the "Octavia" with nearly similar engines, by the same firm, affords proof convincing enough, that economy is as easily attained by proper arrangements at sea as on land.

We may here remark that the "Italia" is not a new ship, and has been previously fitted with engines of about 110 nominal horse power, by Messrs. Rowan. The speed attained not being considered satisfactory, these have been replaced by the present engines.

The trial trip took place on the 19th inst., when the ship left her moorings off Gravesend, at about half-past eleven o'clock in the forenoon, and ran down to the measured mile at the Maplin sands. Although this was but the third time the engines have been under steam, they worked perfectly satisfactorily, without trouble from heating or any other cause. Four runs were accomplished, the average results of which we give below. On their conclusion, the vessel returned to her former berth.

	ft.	in.
The length of the "Italia" between perpendiculars is	210	0
Breadth, extreme	28	0
Depth of hold	16	6
Builder's tonnage	800 tons.	

Her engines are of 120 horses' nominal power, and have three cylinders, each 40 in. diameter, with a stroke of 2 ft. 6 in. working on to a 3-throw crank shaft, with the cranks set at 120 deg. to each other. The cylinders are jacketted round their circumference and at their ends, and are intended to work with steam of a pressure of 25 lb. to the square in. The collective area of the pistons is about one-half greater than in ordinary engines of the same power, it being intended to realize four times the nominal power, with the steam cut off at one-fifth of the stroke. The steam is shut off entirely by the slide valve, without the use of the ordinary expansion valve. The slides are specially adapted for this purpose, being double-ported, so far as the eduction passages are concerned, but having three steam openings, in order to give the requisite area for admission. They are worked by a shaft, with suitable cranks, running across in front of the valve chests. This shaft is driven from the main crank shaft of the engines by a system of wheel work, the two intermediate wheels of which are mounted in a moveable frame, which may be raised or lowered at pleasure, the effect of which is to vary the position of the cranks on the secondary shaft in relation to the position of the engine cranks. By this means, the steam may be shut off at any part between one-fourth and one-seventh of the stroke, and by the same means, the slide cranks may be shifted into the proper position for reversing the engines. There are two surface condensers, which are placed, together with their air-pumps, on the opposite side of the vessel to the cylinders, and facing the two outer ones. The space between the condensers, over the cross-heads and piston rods, is occupied by the engine platform. By this arrangement, all the working parts are brought well in view, and are easily reached by the engineer on the platform. The condensers are a modification of Hall's, in which the condensing water surrounds the exterior of the tubes, while the steam is condensed within them. In this case, the tubes are placed in a position inclined from the horizontal line, with covers forming chambers at each end; the exhaust pipe from the cylinder is brought into the chamber at the highest end of the tubes, and the condensed water is delivered into that at the lower end, from which it is conveyed to the air-pump. This arrangement leaves both ends of the tubes conveniently exposed when the covers are removed, while at the same time a space is left below the tubes for any mud that may be carried into the condensers to settle, and from which it can be easily removed. The water is driven through the condensing tanks by a plunger pump, fitted with *lignum vitæ* packing and india-rubber foot and delivery valves. This pump is placed opposite the middle cylinder, and worked by a rod direct from its piston. The condensed steam is pumped by the air-pumps into an open cistern, from which it is forced by the ordinary feed pumps into the boilers.

In the uptake of the single four-furnaced boiler is fitted a superheating apparatus, as patented by Mr. Field, which consists of a series of flattened tubes, through which the steam passes on its way to the engines. These tubes are placed in rows one above the other, so as to offer the least possible obstruction to the heated gases passing to the chimney; and the apparatus is so constructed that any of the tubes may be readily taken out and renewed should they at any time become defective, without interfering with the others, while at the same time their exterior surfaces can be easily cleaned from any soot that may be deposited upon them. The screw propeller is three-bladed, and 17 ft. 6 in. pitch. At the trial on the 19th June the draft of the water was 9 ft. 6 in. forward, and 11 ft. 9 in. aft, equal to a mean of 10 ft. 7½ in., with an area of immersed section of 235 square feet. The pressure of the steam was 22 lb., and vacuum 27 in., the engines making 73 revolutions per minute, steam cut off at 1-6th of the stroke. The mean speed of four runs at the measured mile was 11·387 knots, the temperature of the superheated steam being 330 deg., and the indicator showed a mean of 617-horse power. The engines were under the able superintendence of Mr. Warner. So admirable are the arrangements for clothing the cylinders, steam pipes, &c., that the temperature in the engine-room scarcely exceeded that on deck, or under 70 deg. All the arrangements were skilfully carried out under the direction of Herbert Maudslay and Joshua Field., Esqs. The consumption of fuel was, making every allowance, about 2·5 lb. of Welsh coal per indicated horse per hour—a result which speaks for itself.

ON THE FORMS OF THE STRATIFIED ALPS OF SAVOY.

At the weekly evening meeting of the Royal Institution of Great Britain, Friday, June 5, 1863, Sir Henry Holland, Bart., M.D., D.C.L., F.R.S., Vice-President, in the chair, a Paper was read "On the Forms of the Stratified Alps of Savoy," by John Ruskin, Esq.

The purpose of the discourse was to trace some of the influences which have produced the present external forms of the stratified mountains of Savoy, and the probable extent and results of the future operation of such influences.

The subject was arranged under three heads:—

I. The Materials of the Savoy Alps.
II. The Mode of their Formation.
III. The Mode of their subsequent Sculpture.

I. *Their Materials.*—The investigation was limited to those Alps which consist, in whole or in part, either of Jura limestone, of Neocomian beds, or of the Hippurite limestone, and include no important masses of other formations. All these rocks are marine deposits; and the first question to be considered, with respect to the development of mountains out of them, is the kind of change they must undergo in being dried. Whether prolonged through vast periods of time, or hastened by heat and pressure, the drying and solidification of such rocks involved their contraction, and usually, in consequence, their being traversed throughout by minute fissures. Under certain conditions of pressure, these fissures take the aspect of slaty cleavage; under others, they become irregular cracks, dividing all the substance of the stone. If these are not filled, the rock would become a mere heap of debris, and be incapable of establishing itself in any bold form. This is provided against by a metamorphic action, which either arranges the particles of the rock, throughout, in new and more crystalline conditions, or else causes some of them to separate from the rest, to traverse the body of the rock, and arrange themselves in its fissures, thus forming a cement, usually of finer and purer substance than the rest of the stone. In either case, the action tends continually to the purification and segregation of the elements of the stone. The energy of such action depends on accidental circumstances. First, on the attractions of the component elements among themselves; secondly, on every change of external temperature and relation: so that mountains are at different periods in different stages of health (so to call it) or disease. We have mountains of a languid temperament, mountains with checked circulations, mountains in nervous fevers, mountains in atrophy and decline.

This change in the structure of existing rocks is traceable through continuous gradations, so that a black mud or calcareous slime is imperceptibly modified into a magnificently hard and crystalline substance, enclosing nests of beryl, topaz, and sapphire, and veined with gold. But it cannot be determined how far, or in what localities, these changes are yet arrested; in the plurality of instances they are evidently yet in progress. It appears rational to suppose that, as each rock approaches to its perfect type, the change becomes slower; its perfection being continually neared, but never reached; its change being liable also to interruption or reversal by new geological phenomena. In the process of this change, rocks expand or contract; and, in portions, their multitudinous fissures give them a ductility or viscosity like that of glacier-ice on a larger scale: so that many formations are best to be conceived as glaciers, or frozen fields of crag, whose depth is to be measured in miles instead of fathoms; whose crevasses are filled with solvent flame, with vapour, with gelatinous flint, or with crystallizing elements of mingled natures; the whole mass changing its dimensions and flowing into new channels, though by graduations which cannot be measured, and in periods of time of which human life forms no appreciable unit.

II. *Formation.*—Mountains are to be arranged, with respect to their structure, under two great classes—those which are cut out of the beds of which they are composed, and those which are formed by the convolution or contortion of the beds themselves. The Savoy mountains are chiefly of this latter class. When stratified formations are contorted, it is usually either by pressure from below, which raises one part of the formation above the rest; or by lateral pressure, which reduces the whole formation into a series of waves. The ascending pressure may be limited in its sphere of operation; the lateral one necessarily affects extensive tracts of country, and the eminences it produces vanish only by degrees, like the waves left in the wake of a ship. The Savoy mountains have undergone both these kinds of violence in very complex modes and at different periods, so that it becomes almost impossible to trace separately and completely the operation of any given force at a given point.

The speaker's intention was to have analyzed, as far as possible, the action of the forming forces in one wave of simple elevation, the Mont Salève; and in another of lateral compression, the Mont Brezon; but the investigation of the Mont Salève had presented unexpected difficulty. Its façade had been always considered to be formed by vertical beds, raised into that position during the tertiary periods; the speaker's investigations had, on the contrary, led him to conclude that the appearance of vertical beds as owing to a peculiarly sharp distinct cleavage, at right angles with the beds, but nearly parallel to their strike, elsewhere similarly manifested in the Jurassic series of Savoy, and showing itself on the fronts of most of the precipices formed of that rock. The attention of geologists was invited to the determination of this question.

The compressed wave of the Brezon, more complex in arrangement, was more clearly defined. A section of it was given, showing the reverse position of the Hippurite limestone in the summit and lower precipices. This limestone wave was shown to be one of a great series, running parallel with the Alps, and constituting an undulatory district, chiefly composed of chalk beds, separated from the higher limestone district of the Jura and lias by a long trench or moat filled with members of the tertiary series—chiefly nummulite limestone and flysch. This trench might be followed from Faverges, at the head of the lake of Annecy, across Savoy. It separated Mont Vergi from the Mont Dorons, and the Dent d'Oche from the Dent du Midi; then entered Switzerland, separating the Moleson from the Diablerets; passed on through the districts of Thun and Brientz, and, dividing itself into two, caused the zigzagged form of the lake of Lucerne. The principal branch then passed between the high Sentis and the Glarnisch, and broke into confusion in the Tyrol. On the north side of this trench the chalk beds were often vertical, or cast into repeated folds, of which the escarpments were mostly turned away from the Alps; but on the south side of the trench, the Jurassic, Triassic, and Carboniferous beds, though much distorted, showed a prevailing tendency to lean towards the Alps, and turn their escarpments to the central chain.

Both these systems of mountains are intersected by transverse valleys, owing their origin, in the first instance, to a series of transverse curvilinear fractures, which affect the forms even of every minor edge, and produce its principal ravines and boldest rocks, even where no distinctly excavated valleys exist. Thus, the Mont Vergi and Aiguilles of Salouvre are only fragmentary remains of a range of horizontal beds, once continuous, but broken by this transverse system of curvilinear cleavage, and worn or weathered into separate summits.

The means of this ultimate sculpture or weathering were lastly to be considered.

III. *Sculpture.*—The final reductions of mountain form are owing either to disintegration, or to the action of water, in the condition of rain, rivers, or ice; aided by frost and other circumstances of temperature and atmosphere.

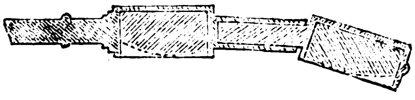
All important existing forms are owing to disintegration, or the action of water. That of ice had been curiously overrated. As an instrument of sculpture, ice is much less powerful than water; the apparently energetic effects of it being merely the exponents of disintegration. A glacier did not produce its moraine, but sustained and exposed the fragments which fell on its surface, pulverizing these by keeping them in motion, but producing very unimportant effects on the rock below; the roundings and striation produced by ice were superficial; while a torrent penetrated into every angle and cranny, undermining and wearing continually, and carrying stones, at the lowest estimate, six hundred thousand times as fast as the glacier. Had the quantity of rain which has fallen on Mont Blanc in the form of snow (and descended in the ravines as ice), fallen as rain, and descended in torrents, the ravines would have been much deeper than they are now, and the glacier may so far be considered as exercising a protective influence. But its power of carriage is unlimited, and when masses of earth or rock are once loosened, the glacier carries them away, and exposes fresh surfaces. Generally, the work of water and ice is in mountain surgery like that of lancet and sponge—one for incision, the other for ablution. No excavation by ice was possible on a large scale, any more than by a stream of honey; and its various actions, with their limitations, were only to be understood by keeping always clearly in view the great law of its motion as a viscous substance, determined by Professor James Forbes.

The existing forms of the Alps are, therefore, traceable chiefly to denudation as they rose from the sea, followed by more or less violent aqueous action, partly arrested during the glacial periods, while the produced diluvium was carried away into the valley of the Rhine or into the North Sea. One very important result of denudation had not yet been sufficiently regarded—namely, that when portions of a thick bed (as the Rudisten-kalk) had been entirely removed, the weight of the remaining masses, pressing unequally on the inferior beds, would, when these were soft (as the Neocomian marls), press them up into arched conditions, like those of the floors of coal-mines in what the miners called "creeps." Many anomalous positions of the beds of Spatangen-kalk, in the district of the Lake of Annecy were, in all probability, owing to this cause; they might be studied advantageously in the sloping base of the great Rochers de Lanfon, which, disintegrating in curved, nearly vertical flakes, each a thousand feet in height, were nevertheless a mere outlying remnant of the great horizontal formation of the Parmelan, and formed, like it, of very thin horizontal beds of Rudisten-kalk, imposed on shaly masses of Neocomian, modified by their pressure. More complex forms of harder rock were wrought by the streams and rains into fantastic outlines; and the transverse gorges were cut deep where they had been first traced by fault or distortion. The analysis of this aqueous action would alone require a series of discourses; but the sum of the facts was that the best and most interesting portions of the mountains were just those which were finally left, the centres and joints, as it were, of the Alpine anatomy. Immeasurable periods of time would be required to wear these away; and to all appearances, during the process of their destruction, others were rising to take their place, and forms of perhaps far more nobly-organized mountain would witness the collateral progress of humanity.

BECK'S READING-LENSES.

Heretofore lenses have frequently been made of such a size that a person can see through them with both eyes simultaneously; but these are massive and expensive. Spectacles have also been made with lenses of considerable magnifying power; but if such spectacles are used as magnifiers by persons having natural eyesight to enable them to see objects placed at, say, four or five inches only from the eye, a considerable strain on the sight is perceptible.

According to an invention, just patented by Mr. R. Beck, of Upper Hollloway, he makes a binocular reading-glass or magnifier by dividing a lens into two equal parts, and mounting the two parts at a short distance apart in a frame but without in other respects altering the relative, positions of the parts, except that with the highest powers he prefers to incline each part outwards to some extent, so that the axis of each half-lens may be inclined in the direction of the object, as hown in the engravings.



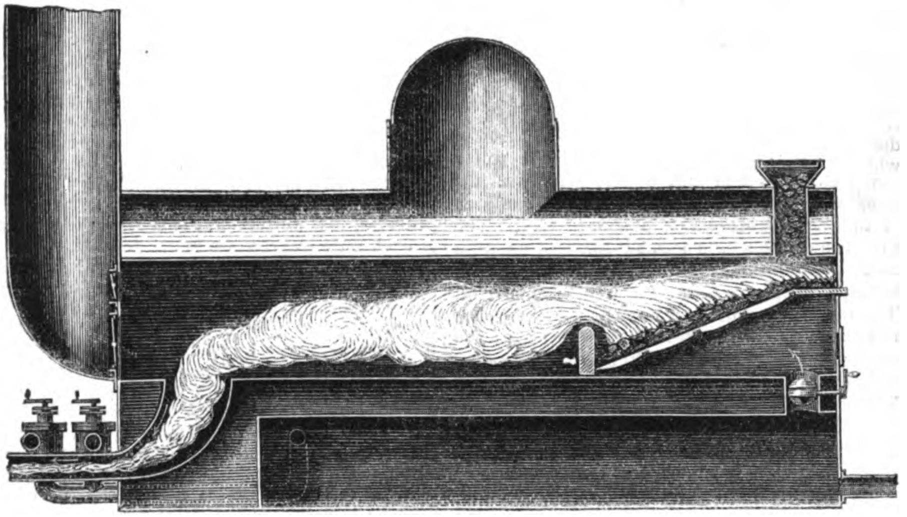
Reading-glasses thus constructed may be used without any strain to the eye being apparent; they are also much more readily constructed and produce less distortion than a single lens of sufficient size to be used simultaneously with both eyes. These advantages become very apparent when the lens is of short focal length, in which case the constructing a single lens of sufficient size becomes practically impossible.

KOPISCH'S PROPELLING, STEERING, AND VENTILATING APPARATUS.

A patent has been obtained by Mr. C. G. Kopisch, of Bishopgate-street, for an apparatus for effecting the propulsion of steam ships or vessels by the injection into the water on which such vessels float of columns or streams of heated air.

The arrangement of the apparatus employed for heating the air may be described as a furnace contained within, and extending from end to end of, an elongated horizontal steam boiler, below which is situated an air reservoir This reservoir is supplied with air by a pumping engine, which shall draw the air from the hold of the ship, with which the various cabins are brought into communication by the air pipes for the purpose of effecting their ventilation. This pumping engine is to be worked by a steam engine supplied with steam from the steam boiler. The air reservoir is brought into connection with the ash-pit of the furnace by pipes, which supply air under pressure to the fire-place. The furnace is connected at its rear end with a chimney by two flues of different diameters, as shown in the above engravings, both of which are capable of being easily closed. From the furnace also lead off air trunks, the outer ends of which open into and below the surface of the water, for the purpose of directing columns of air rearwards, and thereby propelling the ship forwards. The fire-grate being charged with coal from a hopper, and closed to exclude the passage of air, the fire-door is opened and also the larger of the flues leading to the chimney. By this means a draft is obtained to permit of the kindling of the fire and the getting up of steam in the boiler. This being effected and the pumping engine set in action, the flue and fire-door are closed, and air is admitted from the air reservoir to the furnace, the circulation being now maintained by opening the smaller flue leading to the chimney. When it is desired to start the vessel, this flue is also closed, and the heated air and gases of combustion are directed into the water through the propelling air trunks. Other air trunks are also arranged and brought into communication with the main air trunk leading from the furnace, that hot air may be discharged at either side of the ship for the purpose of steering it, and a second set of propelleng air trunks are provided for directing the air forwards, and thus imparting, when desired, a backwsrd motion to the ship.

KOPISCH'S PROPELLING, STEERING, AND VENTILATING APPARATUS.



BROOMAN'S BOILER-TUBES.

FIG. 1.

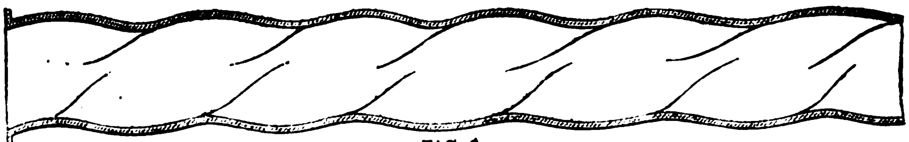


FIG. 2.

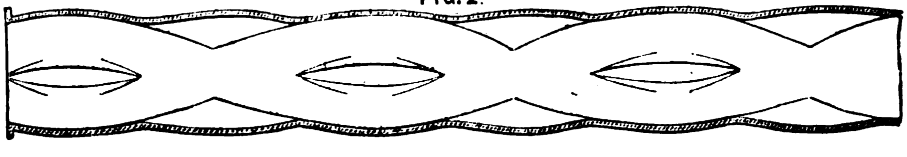

BROOMAN'S BOILER-TUBES.

Mr. R. A. Brooman, of Fleet-street, has just patented, on behalf of Messsrs. Delafond and Corradi, of Marseilles, an improvement in tubes for boilers, condensers, and superheaters. The engravings illustrate two shapes of tubes.

The invention consists in the employment in boilers, condensers, and superheaters of helical instead of straight tubes. The tubes may have one or more turns in their length. The invention also consists in obtaining similar effects in straight tubes to those resulting from the employment of helical tubes, by fixing therein or thereon screw or twisted vanes.

Fig. 1 shows a tube having a single spiral, and fig. 2 a tube with a double spiral.

In boilers, however, in which the products of combustion pass inside the tubes, such vanes will not be applicable, because not being in contact with water they would be rapidly consumed; they apply, however, in condensers and superheaters, and may also be used in boilers with vertical tubes, round the outside of which gases and products of combustion pass.

PROSPECTS OF THE IRON TRADE.

During the last nine months a substantial improvement has taken place in the state of the iron trade of South Wales, and the result is that the works are better employed, and there is a very considerable increase in the number of furnaces in blast. It cannot be said that the trade is in anything like a prosperous state; but the depression of the last four years seems to be gradually disappearing, and a more promising and hopeful feeling has taken its place. The best evidence of this fact is in the actual extension of works that were kept going during the depressed times, and the number of old works that have been, or are about to be, brought into life again. Among the extensions and improvements may be mentioned the lighting of an additional furnace at Ebbw Vale, Abersychan, and Llwydcoed respectively, the erection of a new mill at the Plymouth works, and also extensions at Sirhowy, Aberdare, &c. The old works revived are Varteg, where two furnaces have been put in blast; Golynos, where two others are about to be lighted; and the Cwmbran forge will recommence working without delay. The Venallt furnaces are also likely to be started again, and if the present improving tendency of the trade should continue, there are hopes that something will be done at Hirwain and Treforest. An extensive new establishment—the Marshfield Ironworks, near Llanelly—has lately been started, for the special object of producing armour-plates. These facts, and others which might be mentioned, clearly show that the iron trade of the district is gradually emerging from the depression which has characterized it for so long a time.

The make of pig iron in South Staffordshire is to be reduced by the blowing out of blast furnaces. Several have been blown out during the last week, and it is expected that some other makers of pig iron will follow the example. Mr. Benjamin Gibbons blew out one at Millfields on Saturday, and contemplates blowing out another. Messrs. Turley, of Coseley, also blew one out on Monday; and Messrs. Colebourne, of Tipton, have done the same. The Parkfield Company and Messrs. Cresswell have also determined to blow out a furnace each. This, as we have previously stated, is, in the present state of the trade, the only course open to prevent the price of pig iron falling below remunerative rates.

The iron trade of France is very unsettled owing to the state of affairs in Russia and Prussia. Some orders for pig iron were received at St. Dizier last week to be executed within a limited period. Buyers in general impose this condition when they are aware that the ironmasters are not overburdened with orders. The stock in hand at present is not large, as the orders have been latterly so limited that ironmasters have manufactured barely sufficient to satisfy the demand. Ironmasters are asking for the present from 225f. to 230f. A letter from Longwy, in the Moselle, says, that although the demand for iron is good, and that the ironmasters have orders on hand, it is not possible to make the slightest increase to existing prices. The manufacturers of rails are working in anticipation of the orders they expect to receive from the railway companies engaged in constructing new lines. These companies have not yet concluded many contracts with the ironmasters. Railway directors are not yet decided as to what price they ought to offer, and ironmasters are uncertain as to the price they ought to ask. It is expected that when one railway company shall have concluded a large contract by which the price of rails shall be fixed, all the others will follow.

PURIFIED COKE FOR IRON SMELTING.

M. E. Kopp, a German chemist, describes the following mode of purifying coke, a subject of considerable interest both to coal mine proprietors, and ironmasters.

After the conversion of coal into coke in the usual way, it is taken red-hot from the furnace. In well-constructed coke-furnaces this is effected mechanically; the furnace is open at each extremity, and a very thick, shield-shape plate of cast iron, adjusted to a strong-toothed rod of iron, which is propelled with great force by gears, gradually pushes before it, and finally expels from the furnace, in a single block, the whole of the prepared coke. The incandescent coke is generally extinguished by throwing a large quantity of water over it. This water it is proposed to acidulate with hydrochloric acid.

The incandescent coke may contain protosulphide of iron, proceeding from the pyrites, which at red-heat have lost half their sulphur, sulphide of calcium proceeding from the reduction of sulphate of lime, phosphates, silicates, &c. By contact with the diluted hydrochloric acid, the sulphides of iron and calcium are transformed into chlorides of iron and calcium, with disengagement of sulphuretted hydrogen, which is carried away by the water vapours, escaping abundantly when the coke is extinguished. The phosphates are converted into soluble biphosphates, and even the silicates may be attacked; the bases dissolve as chlorides, a portion of the silica at the same time becoming soluble, which happens when a silicate is digested, hot, in a very diluted acid. Were the coke merely sprinkled with hydrochloric water, and allowed to dry immediately from the heat retained in it, even when the burning had ceased, the chlorides, biphosphates, and silica would remain; but certainly the sulphuretted hydrogen, and with it nearly all the the sulphur, would have been eliminated. But, on the contrary, if the coke were impregnated with acid solution, and were then washed with water, a large portion of the impurities specified would be expelled by the washing. The washed coke can then be dried, either in the air or by the unutilized heat of the coal kilns. To impart to it still more the qualities of charcoal, it may be sprinkled with a weak solution, or powdered over with dry carbonate of soda, as free as possible from sulphate.

The carbonate of soda, prepared by means of cryolite (double fluoride of aluminium and sodium), naturally containing no trace of sulphate, answers best for this purpose.

In most instances finely-powdered cryolite may be used with advantage, and ⅓ to ½ per cent. added to the coke. Cryolite supplies economically the alkali which the coke lacks; and though the soda exists in this mineral in the state of fluoride, there seems no doubt as to its beneficial influence.

We have had occasion to make several trials in fusing cast iron and steel with coke purified by weak hydrochloric acid, with the addition of a little carbonate of soda, and the results were decidedly favourable, as compared with those obtained with ordinary unprepared coke.

Finally, we think that a series of experiments should be undertaken, to ascertain what effect cryolite used in blast furnaces would have on the yield and on the quality of cast iron, and in puddling furnaces on the properties of puddled steel. Cryolite is found in very large masses in Greenland, and the price will decrease as the applications of it become more numerous.

SIR GEORGE GREY AND ROAD LOCOMOTIVES.

A short time since a case came before the Wiltshire county magistrates at Salisbury, when a Mr. Rowland, the owner of a locomotive engine, was summoned for allowing it to remain on the highway in the parish of Britford. The summons was issued under the Highway Act, at the instance of Viscount Folkestone, who was very desirous that the question as to the right of running engines on the highways should be tried. It was argued, on the part of the defendant, that the Act of Parliament passed in 1861 repealed the clause in reference to locomotives in the Highway Act, and the case was adjourned in order that the opinion of the Home Secretary might be obtained. Lord Folkestone did not write to Sir George Grey, but applied to Baron Wilde, who gave it as his opinion that the use of locomotives along a high road was legal. If they were driven too fast, so as to cause a nuisance, then the owner could be indicted, but there was no penalty recoverable under the Highway Act. During the past week the Wiltshire magistrates have received the following letter from the Home-office, which decision is of considerable importance to engineers:—"Sir,—I am directed by Secretary Sir George Grey to acknowledge the receipt of your letter of the 9th inst., and to inform you that, in compliance with the wishes of the justices of the division of Salisbury and Amesbury, Sir George Grey has this day issued an order, which will appear in the *Gazette* of next Tuesday, prohibiting the use of any kind of locomotive whatever propelled by steam, or any other than animal power, on the highways within the several parishes comprised in the above-named division, excepting between the hours of 9 o'clock at night and 7 in the morning.—I have the honour to be, &c.—H. A. Bruce."

INFLUENCE OF FROST ON IRON.

The following extract from Kirkaldy's work on iron and steel goes far to prove that the effect of cold on the strength of iron is less injurious than is generally imagined:—Frost being considered to act injuriously on the strength of iron, some experiments were made during the severe weather in Dec., 1860, to ascertain its effects. A bar of Glasgow B best, ¾ in. diameter, was converted into ten bolts, in the ordinary way, six were exposed all night to intense frost, and tested in the morning with the thermometer at 23 deg. Fahr. The other four were kept in a warm place, and carefully protected during testing. Three were tested with gradual, and seven with sudden strains; it was found that when the strain was gradually applied there was very little difference between the specimen tested in the ordinary condition and the two that were frozen; the former bore 55,717, the latter 54,385; difference, 1,332 lb., or 2·3 per cent. less. The difference under sudden strains is somewhat greater, viz., 3·6 per cent. less when frozen. The load just sufficient to cause rupture was in the one case somewhere between 50,535 and 49,948; in the other, between 49,060 and 48,100; the mean in the one instance being 50,391, in the other 48,584; difference, 1,807 lb., or 3·6 per cent. The writer regrets that other duties prevented him from carrying out his intention of repeating these experiments with bars of various qualities. It will be noticed that the bar tested happened to be of superior quality: had it been of a coarser description, the difference when frozen might have been much greater. The frozen bolts were coated with a thin layer of ice, for the purpose of better observing the effects produced. In specimen, with strain slowly applied, the ice gradually became opaque and white, and just before breaking it resembled hoar frost. In another specimen, under sudden strain the ice remained transparent, and the instantaneous stretching of the specimen, was most beautifully exhibited by the ice cracking and forming a series of complete rings. In yet another, the strain was greater than in the last, and caused the rupture of the specimen; the heat thereby generated was apparent by the ice melting, and in the formation of vapour.

WORKING BEAM ENGINES.

It is not a little remarkable, in the history of the present struggle, that the beam engines in the naval service should have escaped material injury—that all steam engines, in fact, above and below the water line, have been but slightly damaged, considering their exposure. He would have been a rash man who had predicted at the beginning of the rebellion that steam machinery in our gunboats would have escaped, while the hulls of the ships themselves have been riddled by the fire from forts and batteries with which they have been engaged. Of course, when it has been necessary to blow up some of our vessels, the engines have been scattered, with the other fragments, to the four winds of the earth; but we have not yet upon record any instance where a beam engine particularly has been entirely crippled for any length of time, still less destroyed. When the wrought-iron strap of a working beam breaks, the skeleton is also fractured, the piston is forced out through the cylinder head, the front links are bent, the frame is thrown out of line, in short, there is dire confusion and utter wreck. It is a comparatively easy thing to predict what would occur in case a huge round shot struck a working beam; in fact, there is no question but that it would place the machine *hors de combat* instantly. Since, however, we have no data to refer to, no such incident having ever taken place, all inferences are gratuitous. It is noticeable that the steam machinery of our wooden vessels and iron-clads have performed well, and that no accidents of a general nature have taken place, showing them to be unreliable in time of need. Had any one of the "Monitors" or the "Ironsides" become unmanagable before Fort Sumter, they would, ere this, have been resting upon the bottom of the harbour, and the fact that they peformed well generally is creditable to the skill of our engine-builders. The gunboats maintain their stations on the blockading squadron and are not continually running home for repairs; and whether they attain as much speed as would be desirable or not, it is certain that thus far they have done the nation good service in a time of need.—*Scientific American.*

The new saloon steamer "Iona" is reported to have run the lights in 45½ minutes, being the greatest rate of speed ever attained on the Clyde.

KLEIN'S TURNING LATHE.

FIG. 1.

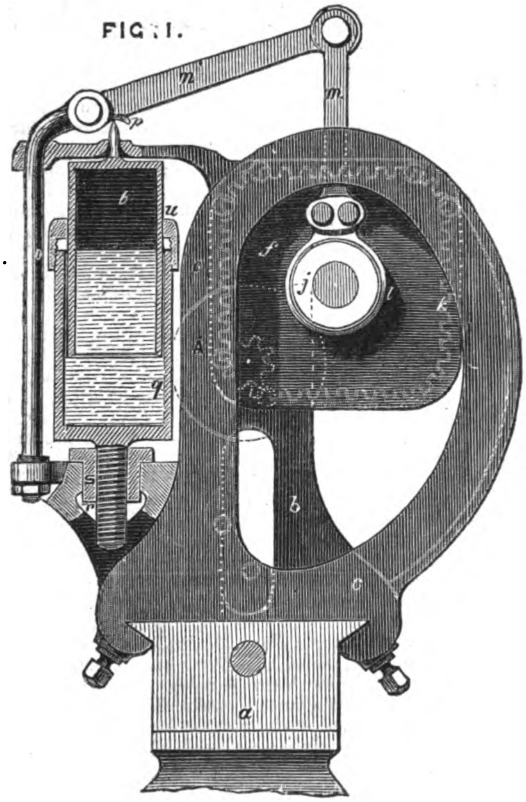

FIG. 2. FIG. 3

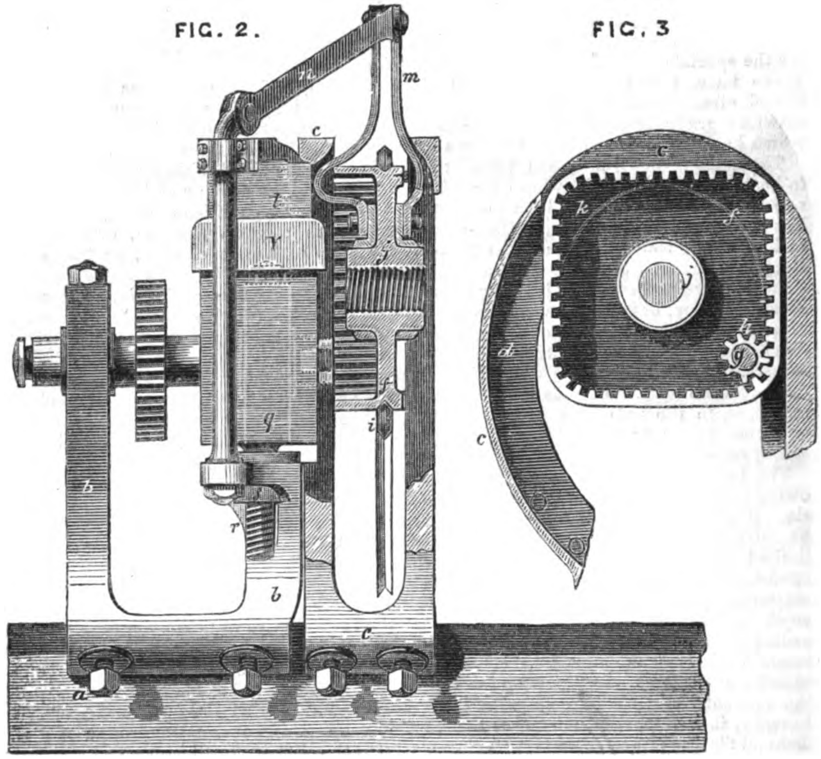


KLEIN'S TURNING-LATHE.

A patent has just been obtained by Mr. P. H. Klein, of Paris, for an invention for improvements in machinery for turning or shaping. The invention consists in the employment of machinery in combination with an ordinary turning-lathe, for shaping metals and other substances, square or polygonal, instead of round or oval as hitherto. The invention will be best understood by reference to the accompanying engravings—fig. 1 of which is an elevation, partly in section, of the end of a lathe with the improved machinery applied thereto; fig. 2, a longitudinal elevation of the same; and fig. 3, a face view of the frame or carrier for carrying the article to be shaped, and of a guide in which it turns, as hereafter explained.

The bed *a* of the lathe, with its puppet *b*, carries a guide *c*, in the thickness of which is formed a groove *d*, in which a moveable frame or carrier *f* works. The guide *c* is free to slide on the bed *a*. The principal shaft *g* is threaded at its extremimity as in ordinary lathes, and carries a small pinion *h*, held by a screw-thread, and in gear with a toothed rack *k* on the interior of the frame *f*. The frame *f* thus bears against the guide *c*, and it carries small rollers *i*, *i* to facilitate its movement in the groove *d*. The rack *k* is rounded at the corners, so that it may always be in gear with the pinion *h* which drives it; it may be cast in a piece with the frame *f*, or it may be cast separately and fixed to it by screws. In the centre of the frame *f* is a socket *j*, threaded on the inside for receiving the article to be shaped. This socket is supported by a collar *l*, held by two arms *m*, *m*, united by hinge-joints to a lever *n* connected to a support *o* fixed to the frame of the guide *c*. The internal groove in the guide *c* is interrupted at A, to allow of the passage of the rollers *i*, *i* when the frame turns. The lever *n* rests upon a point *p*, projecting from the top of a suspension puppet, which is arranged as follows:—A vessel *q*, containing water or other liquid, carries at bottom a screwed rod *r*, which takes into a threaded nut *s* resting upon the frame of the puppet. An inverted vessel *t* descends into the liquid in the vessel *q* to form a hermetic joint, aided by a socket *u*, which is screwed on the upper part of the vessel *q*, and makes a stuffing box. The lever *n* presses upon the point *p*, and causes the vessel *t* to descend in the liquid in the vessel *q*; the air held in the vessel *t* is thereby compressed in such a manner as to form a balance or equilibrium to the weight of the frame *f* and the object carried by it and under work. The pressure is regulated by raising or lowering the vessel *q* by means of the nut *s*.

The arrangement just described is applicable to chuck-lathes—that is to say, those lathes in which the article to be shaped is fixed on the nose of the lathe, no back centre being required. When it is desired to turn articles the length of which necessitates a back centre, a parallel lathe is employed with two similar puppets, one of which serves as a back centre to the other.

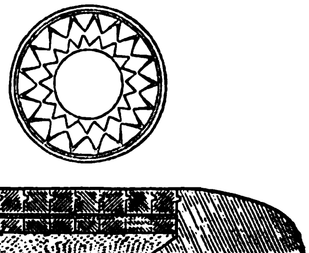
Articles of round shape may be turned by the arrangement before described by removing the pinion *h* and employing an ordinary turning tool. The frame *f* is maintained in a vertical plane during the working of the machine by the pinion and by the cheeks of the rack, as well as by the groove *d*, in such manner that, upon being caused to slide in the groove by means of the pinion *h*, which is fixed on the principal shaft, it presents the several faces of the article being shaped successively to the cutting or shaping tool.

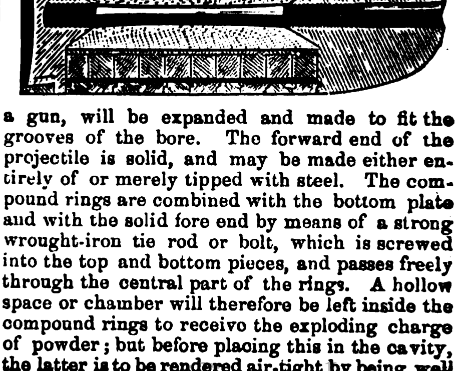
PALMER'S PROJECTILES.

An invention of improvements in hollow projectiles has recently been patented by Mr. F. Palmer, of the Strand. The object of the invention is, first, to construct a hollow projectile in such a manner that its flight shall be true and not erratic, and that, whatever the range may be, the projectile shall strike the object with the point or fore end foremost. This is effected by distributing the weight in such a manner that the fore end or forward half of the projectile, except bomb shells, which must be spherical, shall contain a large excess, say, about two-thirds, of the entire weight.

Another part of the invention consists in constructing the projectile of a series of single rings, or compound rings, composed of two, three, or more single rings, arranged and formed in such a manner, that on the projectile exploding the rings shall be subdivided into a large number of pieces of nearly equal dimensions, and of such a weight, that any piece, by its mere gravity or weight when falling from a height, will be sufficient to kill or seriously injure a man.

The compound rings are made of metal, and consist of a series of diamond or wedge-shaped pieces assembled together in an annular form, and so constructed that each set of rings will fit into one another so as to form a flat compound ring with an open centre. Any conveninent number of these compound rings may be piled one upon the other on an end plate, the outer end of which (if the projectile be intended for a rifled gun) may be provided with a washer of brass or soft metal, which, upon the projectile being fired from a gun, will be expanded and made to fit the grooves of the bore. The forward end of the projectile is solid, and may be made either entirely of or merely tipped with steel. The compound rings are combined with the bottom plate and with the solid fore end by means of a strong wrought-iron tie rod or bolt, which is screwed into the top and bottom pieces, and passes freely through the central part of the rings. A hollow space or chamber will therefore be left inside the compound rings to receive the exploding charge of powder; but before placing this in the cavity, the latter is to be rendered air-tight by being well





WHITAKER'S PULPING AND SLICING MACHINE.

FIG. 1.

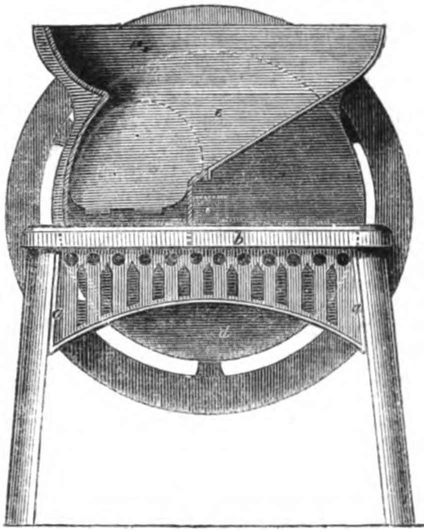


FIG. 2.

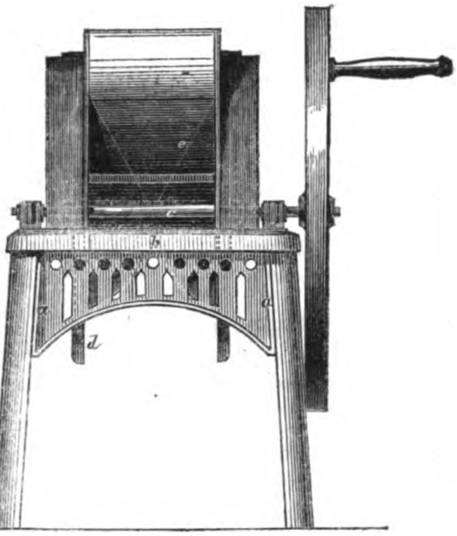

FIG. 3.

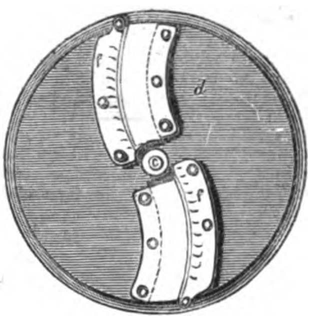

FIG. 4.

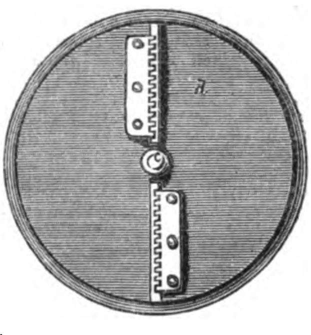

paid over with strong paint of white lead, zinc, or other suitable composition, which will close the interstices between the rings. Projectiles on this principle may either be made cylindrical or elongated with conical or pointed ends, or they may be made spherical like ordinary bomb shells. The engravings clearly show the invention.

The projectiles may be provided with a common fuze, which will be ignited by the propelling charge in the ordinary manner. A percussion fuze may also be employed to explode the internal charge when the projectile strikes any object; it is therefore of the greatest importance that the flight of the projectile should be accurate, and that it should not be liable to turn end over end in the air before it strikes the object.

By subdividing the compound rings into separate rings, each composed of a series of pieces of a wedge or diamond shape, or other suitable form, it will be understood that, upon the explosion of the internal charge taking place, the rings and discs will be split up or divided into a vast number of fragments, and will be thrown with such force that each fragment will be capable of killing or disabling a man.

WHITAKER'S PULPING AND SLICING MACHINE.

Heretofore the pulping, stripping, and slicing of roots for cattle food have been done in two or more machines. Mr. J. Whitaker, of Leigh, Lancaster, has patented an improved machine whereby the above operations can be effectually done in one apparatus. Fixed to the driving shaft at each side of the machine is a fly-wheel, one mounted with one or more knives for slicing, and the other with the knives or tools for pulping. The stripping knives or tools are fixed upon separate plates which when required are screwed to the slicing wheel, there being slots in the wheel to allow the tools to pass through the interior. The hinged guide or plate is placed in the centre of the hopper, and can be turned on either side so as to guide the roots to the pulpers on one of the wheels, or to the slicing knives or strippers on the other wheel, by which means the three operations of pulping, slicing, and stripping can be performed at different times in the same machine. The rims of the wheels turn in grooves formed by beads in the sides of the hopper in order to enable the knives or tools to be quite close to their work, and thereby slice, strip, or pulp the last piece, and the sides of the hopper are curved and sloped to allow the matters to be delivered from the machine with perfect ease.

a represents the framework of the machine; *b*, the bed or table; *c*, the driving shaft; *d*, the plain wheel to which the slicers, pulpers, and strippers are attached; and *e* the hinged guide or plate for leading the roots to the slicing or stripping knives on one side or to the pulping knives on the other side. The pulpers are on one wheel, and the knives for slicing on the other wheel; and when stripping is required to be performed, the plates *f*, fig. 3, with the strippers in them are fixed to the wheel; but when slicing is to be performed, the strippers are removed. Thus by fixing on the driving shaft two wheels mounted with the necessary cutters or tools and using the hinged guide to lead the roots to one side or the other, the several operations of pulping, stripping, and slicing edible roots can be performed in one machine.

FLAX-SCUTCHING MACHINES.

Now that so much attention is deservedly given to the cultivation of flax, it becomes of the highest importance to obtain an efficient scutching machine. At the late Agricultural Meeting at Lille, where large quantities of flax are cultivated, a gold medal was offered for the best scutching machine. We believe there were about forty competitors, and are gratified in stating the medal was awarded to the scutcher invented by Messrs. Rowan, of Belfast, and exhibited by Messrs. Le Conte, of Morlaix. In this machine the beaters are thrown out by centrifugal force, but by being loose in their bearings, they exert only sufficient power upon the flax to beat out and separate the loose and woody particles from the fibre without tearing or injuring it. Very little tow is produced. One advantage possessed by the machine is that its price puts it within reach of the small flax-growers.

THE MANUFACTURE OF COMPOSITE CANDLES AT CLICHY.

The manufacture of stearine* is essentially French—from the first works of MM. Chevreul and Gay-Lussac in 1824, and the industrial realisation of MM. de Milly and Motard in 1835, down to the recent idea of decorating the wax candle, and making it an ornament which completes the luxury of candelabra. The numerous inconveniences of the candle, its nauseous odour, its insufficient consistency, its smoky wick requiring snuffers, added to the high price of wax, stimulated the inventors in their researches. As in a great number of industrial operations, the spirit of fraud guided the wax-chandlers. They commenced by making tallow candles coated with a layer of wax; but the fraud was discovered quickly enough by the fœtid emanations arising therefrom. They mixed with the wax different kinds of flour—beans and horse-chesnuts. They also tried to fabricate tallow candles which appeared to be wax; but this did not give very satisfactory results. The wick was always smoking, the snuffers necessary, and the candle, disguised under divers names, continued to soil the hands, and to stain the clothes and furniture. It was reserved for MM. Chevreul and Gay-Lussac to discover, in 1825, the principles by the aid of which MM. de Milly and Motard, assisted by the researches of M. Cambaceres, should, in 1835, lay the foundation of an entire industry, one of the most flourishing of the present day—the fabrication of the stearine wax candles. The trials of experience had been fruitless; it was the methodical researches of chemistry which triumphed with *eclat*. They had a portion of tallow analyzed, which they found composed of three acids—stearic, margaric, and oleic, with a base termed glycerine, the first acid fusible at 60 deg., the second at 47 deg., and the third liquid at 0. They analyzed the three acids, and they discovered that they were formed of carbon and hydrogen, together with a certain quantity of oxygen, which was the most favourable composition to produce by combustion a brilliant light. In fact, they contained hydrogen, the most inflammable of gases; oxygen, without which all combustion is impossible; and finally, carbon, the disengagement of which puts in suspension in the flame of the hydrogen little corpuscules which, passing to a reddish-white, give brilliancy to the flame. Of the three acids, two were, by their physical properties—that is to say, by their consistence and whiteness—in the best condition possible for making the wax candles. The third, on the contrary, by its extreme fluidity, was an obstacle that it was necessary to surmount. Its reddish colour, the volatile matters that it contained, the smoke that is disengaged by an excess of carbon, rendered it unadapted for luxurious lighting. These principles once laid down, we perceive the means they used to obtain, in their purity, the stearic and margaric acids; they mixed the melted tallow with a base of soda or potash, and they thus got rid of the glycerine, which could be of no use. By adding a certain quantity of sulphuric acid, which has an extreme affinity for bases, they formed a sulphate of soda, and the three fat acids were set at liberty in a state of paste; the solid crystals of the stearic and margaric acids containing in their network the fluid oleic acid. An energetic pressure disengaged it mechanically, and the two acids remained pure in a state of white matter like alabaster, solid enough, and fusible at about 55 deg.

---

* Stearine (from *stear*, suet), that part of oils and fats which is solid at common temperatures. The nature of these substances was first made known by Chevreul, in 1823, who showed that they were compounds of peculiar acids, with a base termed glycerine; of these compounds the chief are stearine, margarine, and oleine (from *elaion* oil).

Towards 1835, the application commenced on a great scale at the Usine de l'Etoile, extending into Germany, where the Austrians distinguished themselves notably in the manufacture, which established itself in England, where the powerful firm of Price and Co. produce immense quantities of fat acids, and now all nations make large quantities of the stearine wax candle, more or less handsome, particularly since the economical method of distillation has allowed a decrease in the price by making use of matters of less value, such as palm oil and all kinds of inferior fats.

The manufactory at Clichy, the description of which will give us an opportunity of furnishing a detailed account of the making of candles, is the last established. The company has studied rather to introduce processes for the purpose of bringing the manufacture to perfection, than the erection of one of those immense buildings that swallow up the bulk of the capital, leaving little or no residue for the carrying on of the business. The tallow factory, however, is necessarily a vast edifice, and its chimney is one of the highest. The only object of the company has been the manufacture of irreproachable products, and to raise the character of its manufacturing mark. Let us see what series of operations resulted from this. The first is the melting of tallow. No industrial manipulation is more infectious or more nauseous—none more repulsive for the neighbours. The factories where it is carried on are built as far as possible from the centre of habitation. The authority for establishing them is a sort of privilege. The use of the tallow candle, which scarcely extended to the South, where oil was abundant and very cheap, was extended, and became perfected in the North of Europe—in particular, in France. The butchers themselves melted their fat and made candles of it, towards 1016, a corporation of chandlers was established by Philip I., re-arranged towards 1470, and kept its privileges to the end of the last century. Moreover, without being as much shackled and as well regulated as formerly, it is, however, practised under a very active superintendence of the police prefecture and of the supervision of the butchers of Paris. The tallow arrives at the manufactory *en branche*, that is to say, as it comes from the offal-houses and butcheries. The sooner it is brought the better, especially in summer; in fact, the fat-matter is enveloped in fibrous cells, eminently liable to putrefaction, which decomposes rapidly at their contact. In order to disengage these fat-matters from the membranes which envelope them, two means are employed: the most ancient consists in melting the tallow in copper pans, then to extract, by strong pressure, all the liquid part, and having for remainder *des cretons* (the residue of tallow) in little loaves. The procedure employed at Clichy consists in reducing the fusion of the tallow into a liquid with an addition of sulphuric acid, which destroys completely all the membranes, and brings with it a certain quantity of glycerine, when they pour the mixture into large vats, capable of containing four or five thousand kilogrammes; they barrel up the tallow, after having previously added a little water and sulphuric acid; they then introduce a current of vapour at 133 degrees, by means of a serpentine pipe, perforated with little holes; ebullition commences, the cells open, and the membranes are destroyed. At the end of four hours, it is poured into crystallizing copper vessels and left to cool; they then rack and leave it to settle in forms of wood named *jalots*. The tallow then takes the form of cone-shaped loaves. By this process they withdraw about 88 to 100 per cent. of useful matter, already white, purified from all organic bodies not belonging to it, leaving a little glycerine, which it is necessary to get rid of altogether. This object is attained by saponification, that is to say, by the combination of the fat acids of the tallow with a basis. The tallow coming out of the melting-house in a state of stearine, the margarate and oleate of glycerine are collected in gigantic vats, capable of containing 10,000 kilogrammes of matter, and are put in fusion by means of an injection of vapour, admitted by a serpentine pipe at the bottom of the vat. They add lime, dissolved in water, which soon seizes on the acids, forms stereate, margarate, and oleate of lime. All the glycerine is racked and poured into the Seine, for they have not yet learned how to utilize it economically. The soap obtained by this operation is of a greyish white, and of great hardness. In order to separate the fat acids from it, they pound it, and throw it into great vats, lined with lead, where is already to be found the quantity of sulphuric acid necessary to neutralize the lime; a pipe heats this mixture by an injection of vapour, and soon a sulphate of lime is formed, drawn by its weight to the bottom of the vat, whilst the stearic, margaric, and oleic acids remain on the surface, presenting the appearance of a pretty thick liquid, of a reddish colour, and of a disagreeable smell. A series of canals, of a calculated inclination, conduct into little flat reservoirs, made of iron plates and disposed on props, one beyond the other. The liquid fills the superior reservoir, that which flows over falls into the immediately inferior scale, then into the third, and so on in continuation. In cooling, the matter coagulates, and, drawn from the mould, forms a large square of four centimètres in thickness, by fifty-eight in length and thirty-five in breadth. From these squares it is now necessary to withdraw the oleic acid that they contain. Chemistry is not competent to perform this task; mechanism can succeed, thanks to the hydraulic press. But it is not one simple pressure which can obtain this result; two, three, and even four, are necessary. The first is a cold pressure. The tablets, placed horizontally, enveloped in coarse woollen stuff, horse-hair, or even ordinary hair, called *malfils*, and separated by plates of iron, are piled up under an ordinary hydraulic press, and compressed as much as possible. A great part of the oleic acid contained between the crystals of the two other acids passes off in a reddish-brown liquid, and descends to the cellars, where we shall find it by-and-bye. The cakes, now flattened, still contain a large quantity of the proscribed liquid, as one can judge by the large red spots which mottle them. They then submit them to a final pressure, which should entirely purify them. This pressure, which is accompanied by heat, is effected by means of ingenious machinery, brought to perfection by M. Galabrun. The tablets are placed vertically between horse-hair *etreindelle* covered with a printer's blanket, separated from each other by one of sheet iron, composed of two plates supported by props, leaving between them sufficient space for an injection of vapour, which maintains them at about 80 degrees. The hydraulic press is made horizontally, and, thanks to the clever invention of M. Galabrun, the vapour continues to penetrate between the plates by pipes made of caoutchouc.

The oleic acid squeezed out runs into the inferior part of the preparation, and goes to find that which has deposited itself there in escaping from the cold presses. There they make it pass through felt filters, in which it still leaves a good part of the stearic and margaric acids, which again undergo pressure. The oleic acid, disembarrassed of the useful matters which it contained, is casked, given up to commerce, or employed in the manufacture of soft soap; for the Clichy manufactory, like almost all others, possesses an important soap-making department. The tablets of stearic and margaric acids, freed by the hot pressure of the greater part of the oleic acid, are afterwards employed in making candles. The first kinds for commerce are made thus:—At Clichy the loaves undergo a second hot pressure, and they then obtain the stearic acid almost pure, of a beautiful white, translucent colour, and deprived of odour, of a pretty good resistance to fusion, presenting, in fact, all the qualities which in commerce have given it the name of *extra-double*. In coming out of the presses, the stearic acid is purified by several washings in water, at first acidulated, to purge from all foreign matter, and particularly from the oxide of iron by oxalic acid, to take away every trace of lime, then clarified *a l'albumine*. Thus purified, it crystallizes with an excessive rapidity, which would present a great difficulty in the making of the candle if it were not remedied. Formerly, they added in the coppers a small quantity of arsenic acid, which prevented, it is true, the crystallization, but was entirely injurious to the consumer. In a great many stearine manufactories they employ the old candle-moulds, slightly warmed before pouring in the liquid stearic acid. At Clichy they make use of apparatus by means of which they can easily make 40,000 candles per day. This apparatus has the advantage of being heated and cooled at will, of being worked by women and children, and owes its rapidity of execution to the clever mechanism which supplies it with a series of wicks without end. In coming out of the mould, the candles are exposed to the air on frames of latticework; there they undergo the discolouring influence of light, and become of an absolute whiteness. After forty-eight or sixty hours of exposure, according to the season, they bring them to the cutting machines. An endless chain, composed of parallel staffs, receives each candle at the moment in which, escaping from the notches of the cylinder, it is cut by a circular saw, warmed by friction against two corks, which press it lightly. During their passage on the endless chain, a brush, animated by a to-and-fro movement, washes and rubs the candles, on which fall some drops of water charged with carbonate of soda; from thence they pass over the polisher, a machine in which the brushes are replaced by plugs of flannel, which gently polish the cylindrical surface, and give it an agreeable brightness. The candles are then finished; but their fate varies according to their degree of perfection. Those which contain any defect whatever are broken and again melted down; those which satisfy in every way the experienced eye of the persons charged with the examination of them, are recognized by the house and judged worthy of bearing its mark. By means of a little apparatus in silver, maintained at a heat of about 212 deg. Fahr., they impress the word "Clichy," and the candle goes to the packing-room with its fellows, or, if it present an unusual degree of perfection, it is judged worthy of being decorated. The idea of decorating the candle by ornamenting it with paintings, escutcheons, and figures, is an elegant and graceful invention, that the proprietor of the manufactory, M. Casinberche, has developed with the same certainty of purpose which distinguishes all his enterprizes. Nothing in the world is more unseemly than to see in rich candelabra with costly carvings, or even in small delicate porcelain candlesticks finely painted, thick ugly candles, very unjustly called wax candles, yellowish and dropping grease, with a shrivelled-up wick, emitting with an unpleasant smoke an insipid and repulsive odour.

Exaggerating the contrary idea, the manufactory at Clichy has had the foolish prodigality to paint on the candles some *chefs d'œuvre*, signed by the best names of the manufactory of Sevres; the ever-to-be-regretted Mdme. Laurent, and other artists of talent, have executed charming subjects on stearine. But we must not forget that ornamental painting has its laws. Execute on the candle ornaments of every kind—flowers, birds, chimeras, but do not trace portraits thereon. Nothing can be more tasteful—nothing more simple and more natural—than to have on the candle of which you make use your armorial bearings, if you have inherited them from your ancestors This kind of ornamenting is still expensive, but researches actively and cleverly conducted will soon lead to a reduction in the cost, which will generalize the custom in every house priding itself on elegance.—*Technologist.*

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

All communications should be addressed to the EDITOR, 166, Fleet-street.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

H. K. (Edinburgh).—You will find the slip in our columns of Miscellanea.

H. STAUNTON (Belfast).—Many formulæ are given for determining the flow of water over weirs. Etellweyn's is considered one of the best.

G. B. (Darleston).—There can be no question that cooling either steel or iron in oil confers qualities which can never be gained by quenching them in water. Besides a positive increase of strength, oil imparts a peculiar toughness, which renders this mode of tempering admirably suited to the hardening of saws, &c.

STEAM-PUMPS AT THE INTERNATIONAL EXHIBITION.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

> "Now, the hostility of words we may despise, and even the discourtesy which seems inborn in the American nature we may pass over, however irritating may be sometimes the display of it. But, an actual invasion of our rights it is impossible to disregard."—*The Times.*

SIR,—Will you allow me the use of your columns to state, that I have seen a notice of my Report to the Admiralty on the steam-pumps at the International Exhibition in the *Engineer* of last week (in which my name is actually spelt with an *e* final); and that, while acknowledging the uniform courtesy and gentlemanly reticence (without a taint of provincialism) with which that paper deals with the subject—indeed, I may say with everything it undertakes to criticize—it is, nevertheless, my intention *not* to reply in the columns of the said paper (which are always, no doubt regardless of exposure, most freely placed at the service of correspondents who find occasion to correct the errors of the said paper); but I intend to publish my own account of the trials of the steam-pumps, with every necessary detail of evidence or of explanation, in my work, now in preparation, on "The Exhibited Machinery of 1862."

Possibly the writer of the said article, in the said paper, finds it difficult to forget that little matter of a discussion on boiler explosions, as to which *vide* the Mechanics' Magazine, for May 3rd and 10th, 1861.

I am, Sir, your obedient servant,
D. K. Clark.
11, Adam-street, Adelphi, June 23, 1863.

Miscellanea.

A town in Massachusetts manufactured 1,500 lb. of leather daily from leather scrap and old rope.

Water-tube grate-bars are extensively used for anthracite-coal-burning engines in America.

Steam ports, 18¾ in. long, have been employed in locomotives with 15 in. cylinders.

Iron railroad cars have been used in America. They are too heavy to deserve general adoption.

Steam has been raised in four minutes in the boilers of steam fire-engines.

The repairs of locomotives average 3d. per mile run.

Cast-steel tyres have been successfully welded. The process is both difficult and uncertain.

Messrs. Caird and Co. have received an order from the West India Royal Mail Steamship Company for a screw of 2,434 tons burden, and 500-horse power. The machinery will embrace surface condensation, superheated steam, and a steel shaft by Krupp, of Essen.

Telegraphic communication between Malta and Alexandria has been interrupted for two or three days. This accounts for the absence of telegrams now due with news from India and China.

Those in authoritity seem scarcely satisfied with the prospects of a satisfactory result from the introduction of cupolas on board ships of war, and it would not be surprising if the system of double screws did away with the presumed necessity for employing Capt. Coles' invention.

A good deal has been said lately in London about "steam trumpets" as a mode of signalling on railways. Is appears that these instruments are the invention of a Dr. Upham, of Boston. About a year ago he obtained the use of two locomotives for the purpose of an experimental talk by the sounds of the steam-whistle. The inventor had attached several contrivances to the whistle in the shape of bells, trombones, and clarionets; and by means of these he was enabled to represent the sounds of the alphabet by very different sounds. He found that by their means he could could convey a message to a distance of three miles, which could be heard and understood even amid the more immediate sounds produced by the movement of a railway train. The doctor has, it is said, found it possible, by the simple trumpet, to transmit any message, however long or complicated, the distance of a mile.

An interesting communication from M. Guerin-Menneville on "Silk Culture," was read at the last meeting of the French Academy. This gentleman has succeeded in habituating silkworms, hatched from Japanese eggs (*B. yama-mai*), to feed on oak-leaves, and his Paper was accompanied by some cocoons produced by worms so fed. He expressed hopes that the discovery might lead to the extension of silk culture in France, and we may add that it affords some hope that it might be profitably carried on in England.

The Harbour Trustees have made arrangements to form a west-end harbour at Greenock, of 1,000 ft. in length from east to west, 420 ft. in breadth at the widest point, and 14 ft. in depth at low water, and covering a space of nine acres, or, double the area of the Victoria Harbour. It was proposed to lay the material dredged from the harbour in the timber pond west of Albert Harbour. The new harbour will be wider than the Liverpool docks, with few exceptions.

On Wednesday afternoon, Messrs. Scott and Co., of Greenock, launched from their shipbuilding yard the first of three paddle-wheel steamers for a French firm, the "Compaignie Générale Transatlantique," of 3,250 tons, 346 ft. long, 46 ft. broad, and 31 ft. deep, having side lever engines of 850-horse power nominal, the diameter of the cylinders being 94 in,. and that of the paddle-wheels 36 ft. The vessel was named the "Washington," and is intended for the Havre and New York passage. The company are subsidized by the French Government to the extent of £372,000.

A case was decided in the Jury Court, Edinburgh, before Lord Barcaple, last week, in which Messrs. Cooper and Wood, bottle manufacturers, Portobello, claimed £1,000 damages against the North British Railway Company for injury sustained by the house and grounds of Baileyfield, Portobello, of which the pursuers are proprietors, from smoke, dust, and gases discharged from the defenders' works for converting and hardening iron rails. The works in question were erected about three years ago on a narrow strip of ground left vacant between a curve formed for the improvement of the Leith and Portobello branch line and the original railway track, and they were separated from Baileyfield only by the railway line and the Leith and Dalkeith road running alongside. The pursuers alleged that clouds of smoke and dust, as also deleterious gases, were constantly thrown out in large quantities from 14 low chimneys, rendering the residence at Baileyfield unhealthy and unsafe, or, at least, uncomfortable, and drying up and wasting the trees, shrubs, and vegetation. It was accordingly put in issue whether the house and grounds of Baileyfield were deteriorated by the defenders' works, and the comfort of the occupation impaired, to the nuisance of the pursuers and to their loss, injury, and damage. A large number of scientific witnesses, including chemists, medical practitioners, architects, and horticulturists were examined on both sides. The evidence was to a great extent conflicting, but it seemed to be proved that the vegetation had, since the erection of the furnaces, been considerably injured, and that the comfort of the occupation had been interfered with. The jury were divided in opinion, but by a majority of nine to three they found for the pursuers, with £200 damages.

Mr. Robert Hunt, the keeper of the mining records in the Museum of Practical Geology, London, has published a valuable series of mining statistics, showing the extent and probable duration of the mineral resources of this country. Coals stand at the top of the table, as three-fourths by value of our mineral produce annually consists of this article, so indispensable to our manufacturing and maritime supremacy. We therefore learn, with something deeper than regret, that "the rate of exhaustion which is going on over our coal-fields still increases. From 3,052 collieries, there was used and sold in 1861, 83,635,214 tons. Two million and a-half tons were wasted in the process of working and burned at surface on the collieries of Durham and Northumberland alone. The total waste must, therefore, have been very large, although information thereof could not be correctly obtained." There is, also, a large waste in the actual consumption of coal in this country for domestic purposes, not alluded to by Mr. Hunt, that is not likely to diminish so long as coals are cheap. At present, we probably burn much more fuel in warming our chimneys than our rooms; but, if coals were to be permanently double the price they are now, ingenuity would soon find out the way to utilize that which we now squander. The year's produce from the principal coal-fields is shown by the following figures:—Tons in 1861.—19,145,000 from Durham and Northumberland; 12,196,000 from Lancashire; 9,375,000 from Yorkshire; 7,254,000 from Stafford and Worcester; 6,691,000 from South Wales; 5,116,000 from Derby and Notts; 11,081,000 from all Scotland.

The scientific news from Russia tells us of the discovery of a means whereby the mercury used in the manufacture of looking-glasses may be so hardened as to be rendered defiant of humidity, friction, or blows. The plate-glass thus prepared may consequently be transported to any distance without fear of damage; and the silvering being accomplished by a cheaper process than any yet known, the glass is 10 to 20 per cent. cheaper than at present.

The prizes offered by the Bombay Government, in November, 1862, with the view of stimulating and improving the cultivation of cotton, have been without any effect; and Government now states that the realization of good prices on the spot appears the best and most acceptable reward to the producer. The experiment made with Peruvian cotton seed at Coimbatore, in November last, has proved a failure. The plants appeared for a time healthy and promising, but were entirely destroyed by worms.

We learn from the *Liverpool Albion*, that on Saturday afternoon a new steam fire-engine was tried at the Fire-engine Station, Hatton-garden, in presence of Mr. Clint, chairman of the Watch Committee, Mr. Alderman Houghton, Major Greig, Councillors Crellin and Melladew, Mr. Duncan, the water engineer, and many other gentlemen. The engine was made at the works of Messrs. Lee and Larned, at New York, in which city it is stated to have been in operation for the last four years. It was brought over in the "Great Eastern," and is to be tried at the fire-engine competition in London, on the 1st of next month. It is very powerful and works easily. The steam was got up to working trim in about fifteen minutes from the time the fire was kindled. With a nozzle 1¼ in. in diameter, with a pressure of 80 lb. of steam to the square inch, it threw a stream of water to a height of about 150 ft. The cost of the engine is said to be about £1,000.

The example of England in establishing the noble precedent of International Exhibitions, after finding imitators in the United States, France, and elsewhere, has at last aroused the emulation of the phlegmatic Germans. The free city of Hamburg will next month be the scene of an "International Agricultural Exhibition," to commence on Tuesday, the 14th, and continue one week. This exhibition will be confined to live stock and agricultural productions, including all mechanical aids to agriculture. The Exhibition Committee have entered into negotiations with various steamship and railway companies, to obtain reduced tariffs on freight for contributions from numerous points on the Continent. The most important agricultural societies of all countries, including our own Royal Agricultural Society, have promised to give all the aid and support in their power. The board of directors of the proposed Exhibition—which will be held just outside of the city of Hamburgh—includes men who are prominently identified with commerce, literature, science, and agriculture.

The Staffordshire Rolling Stock Company is announced, under conditions that promise to secure for it a degree of success equal to that attained by similar undertakings now in operation. The object being to construct, purchase, maintain, and lease carriages and waggons to railway companies, collieries, and commercial firms. It is intended to secure an established local company, with a paid-up capital of about £10,000, which is now paying 7½ per cent. per annum. This business is stated to be augmenting, so as to warrant a considerable addition of capital; but no profit or bonus is to be paid upon its sale or surrender. These are favourable circumstances. The proposed capital is £50,000, in £10 shares, and the direction is so constructed as to secure large and valuable connections.

A simple and ingenious apparatus has been invented for indicating to travellers on railways the name of each station as it is approached by the train. Is is in the form of a small dial plate.

A Steamboat in 1788.—In a letter from Dr. Franklin to Dr. Ingenhauz, dated Philadelphia, October 24, 1788, the doctor remarks—"We have no philosophical news here at present, except that a boat moved by a steam engine rows itself against tide in our river, and it is apprehended the construction may be so simplified and improved as to become generally useful."

Clifton Suspension Bridge.—The works in connection with this bridge are now making rapid progress. The last of the nine wire ropes necessary for the construction of the temporary bridge has just been successfully carried across. These iron wire ropes (each of which weighs two tons, and is of extraordinary strength) are now being finally adjusted. Three of them fall upon either side of the position which will be taken by one set of the main chains. These six ropes will be strained up level with each other, and upon them planks will be placed transversely and secured by bolts, forming a platform 7 ft. in width from tower to tower. Two others of the chains will be placed 3½ ft. above this platform, so as to form hand rails to the temporary bridge for the safety of the men engaged upon it. At a greater altitude than all the others is placed the ninth wire rope, on which will run the traversers which will be used in conveying the materials to their required positions. To facilitate the construction of the temporary bridge, a "cradle" has been made, consisting of a light iron frame and wooden floor, 7½ ft. square, which will run on the wire ropes described as the hand-rail ropes. Workmen will be sent out to the middle of the span in this cradle for the purpose of fixing the floor of the platform, and will be propelled to and fro by means of a crab. The ends of the ropes on each side of the river are secured to four balks of timber, which are bolted together, and firmly bedded into the solid rock with bricks and cement. It may be added that the span of the bridge is 702 ft., and the height from the low water to the carriage way 270 ft. The engineers are Messrs. J. Hawkshaw and W. H. Barlow; and Messrs. Cochrane and Co., of Dudley, are the contractors.

The Great Trial of Steam Fire-Engines.—The forthcoming trial of steam fire-engines is fixed to take place at the Crystal Palace on Wednesday next, the 1st of July. The committee, which is presided over by the Duke of Sutherland, offers four prizes—two £250 each, for steam-engines not exceeding 30 cwt., and two prizes of £100 each, for larger class engines not weighing more than 60 cwt., the weights not including coal, water, hose, &c. The authorities of New York have sent over their finest "fire steamer" to compete for a prize. She is named "The Manhattan," and is described as the most efficient for power out of the thousand New York engines. The number of manufacturers who have entered their names for the trial does not exceed 12 or 14. The judges are as follow:—The Right Hon. the Earl of Caithness, the Duke of Sutherland, Lord Richard Grosvenor, M.P., Mr. J. G. Appold, Mr. J. F. Bateman, Mr. W. M. Brown, Mr. T. M. Crampton, Mr. W. H. Crosland, Mr. W. Fairbairn, Mr. T. Hawksley, Mr. J. E. M'Connell, Mr. Henry Maudslay, Mr. J. Matthews, Mr. Nasmyth, Mr. J. Penn, Mr. Smith, and Captain E. M. Shaw, the superintendent of the Fire Brigade. They have selected the northern falls or cascades to the large lakes in the Crystal Palace ground as the site where the different engines will be tested. Captain Shaw has invited the chiefs of the numerous fire corps at Berlin, Paris, Hamburgh, St. Petersburgh, as also at New York, and most of the American States, to London, as his guests, to be present at this trial, which no doubt will be a most exciting affair.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 3163.
Boilers and Furnaces, 3128.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 3139.
Ships and Boats, including their fittings, 3177,
Cultivation of the Soil, including agricultural implements and machines, 3132.
Food and Beverages, including apparatus for preparing food for men and animals—*none.*
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 3131, 3143, 3150, 3152, 3154, 3155, 3156, 3158, 3168, 3169, 3180.
Buildings and Building Materials, 3136, 3138, 3164, 3166.
Lighting, Heating, and Ventilating, 3145, 3147.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 3129, 3130, 3133, 3140, 3142, 3144, 3160, 3161, 3165, 3171, 3174.
Metals, including apparatus for their manufacture, 3153, 3159, 3176.
Chemistry and Photography, 3134, 3157, 3175, 3178.
Electrical Apparatus—*none.*
Warfare, 3135, 3141, 3149, 3173.
Letter-Press Printing—*none.*
Miscellaneous, 3137, 3146, 3148, 3151, 3162, 3167, 3170, 3172, 3179.

3128. J. Napier and W. J. M. Rankine. *Improvements in boilers and valvular mechanism for steam engines.* Dated October 21, 1862.

This invention comprises improvements in the arrangement or construction of boilers for supplying steam to motive power engines, and improvements in the valvular mechanism for regulating the admixture of the steam to such engines, the improvements in boilers being carried out under various modifications. One modification of steam boiler comprised in the present invention is designed more particularly, although not exclusively, for steam of high pressure for marine engines. The boiler consists of four vertical cylindrical shells, with hemispherical tops, and furnaces are formed in the lower parts of two of these shells. The furnace spaces are, at their upper parts, each gradually contracted into a flue, which is bent into a horizontal direction somewhat below the water surface line, and which crosses into one of the two shells having no furnace. In each of these shells the flue is bent downwards and expands into a chamber traversed by vertical tubes having the water inside them, and the fire gases pass downwards through this tube chamber, and off by a flue or uptake rising up centrally between the four shells or boilers. Instead of the flue first rising upwards from each furnace, the furnace and its shell may be constructed to deliver the fire gases directly and horizontally into the flue, crossing into the other shell, and this latter with its tube chamber may be extended downwards considerably below the furnace shell, a fan or other known means being employed to start or ensure a proper draught. The improvements in valvular mechanism relate to that class which contains a double slide and a link motion. In an arrangement embodying these improvements the slide next the valve seat is moved by a pair of eccentrics and a link motion in the ordinary manner, and the position of those two eccentrics on the shaft is fixed with reference to the exhaust only, so as to make it begin and end at the instants most suitable for efficient exhaustion of the steam, without regard to the admission or cut-off. The admission of the steam takes place through a pair of openings in the first slide. The cut-off is effected by means of a second slide behind the first slide. This second slide consists of one plate with an opening in the middle, or of two connected plates with an opening between them, the two endmost edges of which opening overlap the openings of the first slide inwards to the extent required for the lap necessary in order to produce the expansive working. The second slide is moved by means of a third eccentric fixed on the shaft in such a position that the centres of the three eccentrics form a triangle whose acute angles at the centres of the forward and backward eccentrics, respectively, are equal to the angular advance necessary to produce the admission and cut-off required in full forward and full backward gear respectively. The expansion is varied by means of the link motion in the ordinary way. *Patent abandoned.*

3129. W. E. Gedge. *An improved elastic fastening.* (A communication) Dated November 21, 1862.

This invention consists in the application to a glove of any description of a piece of elastic, such as india rubber, covered with silk or other appropriate material, for the purpose of suppressing every description of fastening hitherto used, such as buttons, clasps, or others more or less inconvenient. This elastic fastening (which may be compared to one of the side springs now commonly used in boots), is placed in that part of the glove which encloses the wrist, and in preference beneath the hand. It preserves the shape of the glove, and also prevents its tearing or bursting at the seams, as the glove will yield to every motion of the band. *Patent abandoned.*

3130. D. Saul and M. Morris. *Improvements in crinoline skirts.* Dated November 21, 1862.

This invention consists in making the skirt of a continuous length of crinoline wire or other material, which is wound in a spiral form from one end of the skirt to the other, thus avoiding the necessity of fasteners for securing the ends of the wire, excepting only the fastening at each end of the skirt; the spiral coils of wire or other material must be connected by the usual suspenders. The improved apparatus for manufacturing crinoline skirts consists of a central shaft on which are fixed two or more sets of wires carrying ribs longitudinal with the shaft, the arms of unequal lengths; they are moveable on the shaft, and by varying the position and lengths of the wires, any required shape can be given to the crinoline skirt. As it is desirable in some cases to make the upper part of the crinoline skirt higher at the back than the front, the inventors bind the wire or other material around fixed studs attached to the apparatus above described; these studs are placed at the required distance apart, and as the wire or other material is bent around them, the desired space in front is left open. By this means the abrupt ends of the wires, hitherto unavoidable in making such skirts, are dispensed with. *Patent abandoned.*

3131. J. Steart. *An improved method of extracting the fibre from zostera marina and other aquatic vegetable productions.* Dated November 21, 1862.

In carrying out this invention, the inventor submits the plant or weed to various degrees of pressure, by means of rollers or otherwise, for the purpose of bruising or loosening the outer sheath or skin, and extracting the saccharine matter. He then places it in a mash bath of fresh water at a temperature of form 85 to 110 deg. Fahr. It is then treated in a bath—being a preparation of fish and water, denominated a pure bath—at a temperature from 80 to 110 deg. Fahr. for a suitable length of time; and, lastly, to pressure and friction at a temperature from 75 to 100 deg. Fahr. By this process the outer sheath or skin of the plant or weed is decomposed and removed, leaving the fibre in an uninjured state. It is then dried and cleansed, and fit for manufacturing purposes. *Patent abandoned.*

3132. T. Walker. *Improvements in utilizing sewage matters, and in the means or apparatus employed therein, part of which improvements is also applicable to raising and forcing other fluids.* Dated November 21, 1862.

This invention relates to means by which sewage matters may be collected, and the more solid or heavier fertilizing parts thereof retained by subsidence, and then distributed over a district for agricultural or horticultural purposes. For this purpose the patentee forms a conduit from the sewer or drain to the lower part of a well or reservoir with the side or sides thereof inclined. Whilst the heavier particles will by gravitation descend to the lower part of such well or reservoir, the more liquid portion thereof may flow over by a suitable passage into the sewer or drain again, or into another reservoir or reservoirs. The matter collected by subsidence in the first well or reservoir, he draws from the lower part thereof by means of a pump through suitable piping, and thence by other pipes he conducts it to other tanks or receivers, which he calls field or mud tanks, or reservoirs at distances apart, as may be required. These latter field or mud tanks may be formed deep at one end, inclining upwards to the opposite to facilitate emptying them. The fluid matters from the first well or reservoir may be caused to flow into troughs or gutters laid so as to distribute the fluid matters over the district for irrigation. The pumping apparatus he prefers to employ, and which may be worked by a steam engine, or other suitable power, is formed into a chamber connected to one end, or one to each end, of the working barrel of a pump, having a flexible diaphragm across each chamber to prevent the sewage matters coming in contact with the clean water or oil in the working barrel on one or both sides of the piston. Pumping apparatus similarly arranged is also applicable to other cases where it is desirable to keep the working barrel and piston free from injurious effects of the matters to be raised or forced. Sluices or stop-ways are provided to regulate the direction of the various flows, or to close the passage by any of them as required. *Patent completed.*

3133. C. Wagner. *Improvements in strengthening, securing, and rendering more durable the soles or bottoms of boots, shoes, and other covering for the feet.* (A communication.) Dated November 21, 1862.

This invention consists, mainly, in attaching the outer to the inner sole by metallic rivets or studs, metallic washers being placed over one or both ends thereof. *Patent completed.*

3134. R. W. Swinburne. *Improvements in the manufacture of soda.* Dated November 21, 1862.

This invention consists in manufacturing soda from chloride of sodium fused under heat, by injecting into the fused mass at the bottom, by preference, or below the surface thereof, superheated steam or other suitable gaseous fluid. The agent so introduced is brought into contact with every particle of the fused mass, the chloride of sodium is decomposed, hydrochloric acid is formed and may be secured in any suitable holder, while soda or carbonate of soda remains in the vessel in which the operation has been performed. Instead of acting on the chloride of sodium in a state of fusion, the invention also consists in vaporizing it, and in injecting superheated steam, or other suitable gaseous fluid, into and amongst such vapour while contained in a heated retort or vessel. *Patent completed.*

3135. G. G. Sanderson. *Improvements in armour for fortifications, and floating and other batteries.* Dated November 21, 1862.

For the purposes of this invention, the inventor employs bars of triangular section formed by rolling in a manner similar to that in which railway and other bar iron is commonly made. The base of the triangular section is made flat, and its sides are made the one with a projection and the other with a corresponding recess. The apex of the triangle is, by preference, truncated, and the projection and recess at the sides are conveniently made to occupy respectively about one-half of the length of the side. These rolled bars are to produce the armour placed side by side on a suitable backing or frame, the bars being arranged alternately, so that, if the base of one bar is inwards towards the backing or frame, the bars next it on either side are placed with the bars outwards to form the face of the armour. When the bars are thus arranged, the projection on the one will enter the recess on the other, and so on throughout the series, and the bars form an armour with a flush surface both on the face and at the back. The bars are secured to the backing or frame by bolts at intervals passing through the armour and the backing or frame. *Patent abandoned.*

3136. J. Taylor. *Improvements in the manufacture of tiles, or moulded blocks for building purposes.* Dated November 21, 1862.

For the purposes of this invention, the patentee, in manufacturing moulded, bent, or angular tiles or lumps, each having two outer surfaces at right angles to each other, a die or moulding orifice is so formed that several of such bent or angular tiles or blocks shall be moulded together in one block, and so connected to each other that they may be dried and burned, and transported to any distance before they are separated for use. And the construction of the die or moulding orifice is such that some of the bent tiles (which are all of the same section and dimensions) are within, whilst the others form the outside of the block. The construction of die or moulding orifice preferred is suitable for moulding or forming six bent tiles at the same time slightly connected together, by which not only are they retained in form during the drying and burning processes by reason of the longitudinal interstices or passages, but the processes of drying and burning are facilitated. The die or moulding orifice is of a rectangular figure, and produces four bent tiles, one at each angle of the die, and two similar bent tiles on the inside of the mass, moulded or formed by expressing brick earth or clay through the die. *Patent completed.*

3137. C. A. Orth. *Improvements in apparatus for obtaining and applying motive power.* Dated November 21, 1862.

This invention is carried out in the following manner:—Two sets of rollers or wheels are arranged at one side of the machine; each set is composed of three rollers or wheels arranged one over another, and kept connected by teeth or cogs; the smooth surface of each roller is also in contact with the one next over it. The patentee distinguishes the three rollers of each set as A, B, C, calling the lowest A, the next over it B, and the uppermost C. The rollers A—that is the lowest of each set—are supported on a rack or toothed base-plate. On the rollers C is another rack or toothed plate on which work too other rollers (one over each of the sets A, B, C), and on these rests a beam or bar, which he calls a pressure beam, and to which pressure may be applied by a screw or otherwise. Within each of the lowermost rollers is a smaller roller, on which rests a platform or carriage which supports a contrivance called the union lever, which is placed between the two sets of rollers, and consists of two portions, an upper and a lower portion, held together by guide pieces; each portion is composed of two arms crossing and jointed to each other near one end, and jointed at that end to links or other arms; the arms or limbs of the union lever approach and recede from each other somewhat in the manner of what is called the lazy tongs. To the links are attached arms or bars which he calls balance-pieces. To the rollers B are attached horizontal bars or rods, which are connected to, and actuate, the union lever, and to these are also connected slide-pieces; cross rods are carried from the end of each balance-piece to the centre of the other, where they are connected to the links of the union lever. The whole of the foregoing arrangement of apparatus is repeated at the opposite side of the machine, and angle cranks or angle-cranked shafts are carried from the balance-pieces on each side of the machine to the balance-pieces at the opposite side of the machine. On the cranked shafts are eccentrics which work a compound lever or lazy tongs contrivance, situated between the two arrangements of apparatus. Levers are carried from the cranks to the rollers C to regulate the level. On pressure being applied to the pressure beam, such pressure will be transmitted downward through the topmost rollers and plate on which they rest to the rollers A, B, C, thereby working those rollers to and fro, or inward and outward, in alternate directions, by which means a true level is maintained. The rollers B actuate the union lever which drives the crank shafts, and these transmit motion to the compound lever from which motion can be communicated as desired. *Patent completed.*

3138. S. and C. Deacon. *Improvements in tops, caps, and windguards for chimneys, and in apparatus for cleaning the same.* Dated November 21, 1862.

This inventions consists in constructing the covers of chimney tops, caps, or windguards in such manner that the said covers shall open and close, that is to say, they shall be opened by the brush or ordinary cleaning instrument when it moves upward, so as to allow such brush or instrument to pass up through the top, and shall close or return to their previous position when the said brush or instrument is lowered or withdrawn. The invention next relates to an improved cleaning apparatus, the object of which is to clean the inside surfaces of the guards, shields, or plates fixed outside the openings or slots of windguards, chimneys, or caps. This cleaning apparatus consists of scrapers, brushes, or other cleaning appliances fixed to a ring-band or frame by shanks which pass out through the said slots or openings, the ring-band or frame being within the body of the cap, windguard, or chimney top. When the usual brush or cleaning machine is pushed up against the ring-band or frame, the latter is forced upwards, and of course carries with it the scrapers or other cleaning appliances attached to it, so that these rub against and clean the inside of the guards, and when they reach the top of the slots or openings the brush clears the ring or frame, and the latter drops to its previous position and leaves the brush free to pass upwards. *Patent completed.*

3139. A. Sutton. *An improved construction of time indicator for public vehicles and other uses.* Dated November 21, 1862.

This invention consists in mounting upon any convenient part of the carriage a clock movement provided with a double set of index hands and a divided dial, whereby the hirers of public vehicles may be informed of the amount of fare for which they are liable, and the proprietors of such vehicles of the earnings of the driver. *Patent completed.*

3140. W. E. Gedge. *An improved elliptical compass.* Dated November 22, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3141. W. E. Nethersole and C. Buckland. *Improved safety signals for firearm practice.* Dated November 22, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3142. M. Mishores. *Improvements in the construction of handles for umbrella, parasol, or other like sticks, from soft canes.* Dated November 22, 1862.

This invention consists in introducing a piece of wire through the centre of the cane longitudinally, and then bending it half round, or other suitable shape, at one end to serve for the handle. A little of the extremities of the wire protrudes on each end of the cane, and have a screw thread cut on them, one to screw into the stick of the umbrella or parasol, and the other to screw on an ornament to finish the end of the cane. *Patent abandoned.*

3143. C. De Bergue. *Improvements in machinery or apparatus for the manufacture of metal reeds for weaving.* Dated November 22, 1862.

This invention relates—1, to the application of files for equalizing, rounding, and smoothing the edges and surfaces of flattened metallic wire, as produced by, or after it has come from, the operation of ordinary flatting rollers; 2, to giving a finishing polish to the edges and surfaces of the flattened wire after it has been properly shaped or treated by the filing machine; 3, to making up the prepared wire into reeds. We cannot here give space to the details of the invention. *Patent completed.*

3144. C. Powell. *Improvements in watches and other timekeepers.* Dated November 22, 1862.

The patentee claims—1, screwing the pillars into blank or blind holes; 2, sinking the main spring into the pillar plate on either side; 3, the circular spring click described; 4, the hook; and lastly, connecting maintaining power wheel by two or more slots and screws to the great wheel, all in the manner shown and described with reference to the drawings. *Patent completed.*

3145. W. Clark. *Improvements in candle lamps.* (A communication.) Dated November 22, 1862.

In these lamps the patentee encloses the flame of the candle, or other luminary employed, within a globe or chimney of transparent material, mounted on a socket having an up-and-down movement for the purpose of raising or lowering the globe, so as to enclose or expose the light as desired. This globe may be maintained in position in a self-acting manner by the action of a spiral spring, which raises the socket to its original position, while it, at the same time, may be readily lowered for the purpose of uncovering the wick in order to light it. The candle or taper is enclosed in a socket or tube, being retained therein by a cap fitting on the upper end, or gripping pieces may be applied in lieu of the cap. In this manner the wick will always be on a level with the cap, as the lower part of the candle is pressed upwards by a spring contained within the socket in the same manner as a coach lamp. This lamp is especially applicable on board ship, in which case it is carried in gimbals, in order that it shall retain a vertical position, whatever may be the motion of the ship, while the spiral spring for securing the globe in position on the flame is dispensed with, and a weight applied to the stem of the lamp. *Patent completed.*

3146. A. V. Newton. *Improvements in machinery for cutting corks.* (A communication.) Dated November 22, 1862.

The object of this invention is to cut by a machine directly from a slab of cork wood, corks either of cylindrical form, or of any degree of taper that may be desired; and the invention consists mainly in the use of certain changeable patterns and adjustable screw clamps. The patterns are of cylindrical or conical form, and are attached to, and are concentric with, the rotary shaft or spindle which carries the cutters. *Patent completed.*

3147. J. Webster. *Improvements in the construction of burners and blow-pipes.* Dated November 22, 1862.

The patentee claims—1, the improvements in the construction and arrangement of the several parts of burners, whereby oxygen gas may be supplied to the flame produced by carburetted hydrogen gas, and the means by which the supply of both gases is regulated; 2, the improvements in the construction of wick lamps, by which a current of oxygen gas is supplied to the flame produced by the combustion of fixed oils or hydro-carbons; 3, the improved construction of oxyhydrogen blow-pipe, as set forth and specified. *Patent completed.*

3148. T. J. Searle. *Improvements in apparatus for raising and forcing water or other fluids.* Dated November 24, 1862.

This invention is carried out as follows:—Of any suitable materials, and to any required dimensions, the inventor forms a circular or other shaped framework; and on one or more parts of the same he raises or makes to any required size, and in any convenient position, a sectional chamber or chambers, the same being a part or parts of a circle. He provides an axle, and fits the same transversely in or near the centre of the framework. The chamber or chambers are constructed of metal, or of any other suitable material; and, if two are used, they are fixed right and left of the centre or otherwise; the acute angles of the same are fixed conjointly to, over, and around a part or parts of the axle, or otherwise, and each chamber is made air and water tight. Inside each of the chambers, fixed to, and radiating upon, the axle or other provided axle, there is a single, or, if two chambers, a conjoint moveable limb; the same is made practically to fit and act water-tight in the interior section of the chamber or chambers. A curved rod or rods enters or enter the chamber or chambers through a water-tight package, and the end or ends of the same is or are fixed to the moveable limb or limbs, and it passes through a suitable aperture or apertures into the chamber, or from one chamber into the other, as may be required, for the purpose of conveying the motive power. The moveable limb or limbs radiate or swing to and fro inside the chamber or chambers on the axle or other provided axle. Suitable valves are provided in any suitable part of, or in any convenient position contiguous to, the chamber or chambers, and connected with the same, for the ingress or egress of the water or other fluids. Valves may be inserted in the moveable limb or limbs, if from position or construction used it is necessary. A lever (or levers) of suitable construction, exterior of the chamber or chambers, is fixed on, or radiates on, a part of the axle, and moves the axle, or is fixed on or moves another provided axle to communicate motion either direct to the axle and limb or limbs aforesaid, or to the rod or rods, and is fixed thereto, in any suitable way and part, as may be required. Any other suitable gear may be adopted and used with the apparatus described. The apparatus may also be constructed for a force pump, a carriage engine, or a hand engine, by affixing suitable additional apparatus or means thereto. The entire apparatus may be fixed in any suitable position. In the above description, it is vertical. The motion of the fluids may be either in unity or otherwise. The curved rod or rods, also the axle or axles, used may enter the chamber or chambers at any required part of the same. The entire apparatus may be constructed either single or otherwise, to suit the special purpose required. *Patent abandoned.*

3149. J. B. Howell. *Improvements in the manufacture of armour and other plates, and in shot and shell.* Dated November 24, 1862.

According to these improvements, the inventor takes a number of bars of iron according to the area of the slab to be manufactured. He crosses and recrosses the bars, and distributes them over the area of the slab, and also throughout the thickness it is to be formed; these bars are supported one from the other, and otherwise, so as to present a skeleton (so to speak) of the slab to be formed. The bars, in addition to being crossed, may be in diagonal positions, or inclined to each other in all directions. He disposes this skeleton in a suitable mould, either in a furnace or otherwise, to form the slab or plate; and he then pours into the mould a quantity of what is known as homogeneous iron or cast steel amongst the bars of iron which have been previously heated to a welding heat, and a flux is applied which, together with the heat of the homogeneous metal, causes it to become thoroughly welded to the bars of iron, and become therewith a solid slab of metal. A plate is thus produced having a sufficiently fibrous nature to offer great resistance to the shock of shot, as not only does the fibrous nature of the bar iron remain intact, but the homogeneous metal or steel is much toughened in its nature, at the same time retaining all the known resisting qualities of the homogeneous metal or steel. These blooms or ingots may be subsequently hammered and rolled as may be required. According to the improvements in shot and shell, the inventor forms them of bar or other wrought iron, and makes them with a soft core or centre, covered by a partially converted or steel surface, and all or part of which surface may be hardened. He either first forms the shot or shell of the shape desired, and converts them by the ordinary process of cementation to the depth required, or he only partially shapes them, then converts, and afterwards completes them as desired. In some cases the entire circumference and force may be converted, or it may be the circumference and outer substance of the shot or shell only which is so converted. The conversion he continues till of a depth requisite, and according to the diameter of the shot or shell, and according to the purpose for which they are required. *Patent abandoned.*

3150. W. Clark. *Improvements in the means of obtaining a vacuum or partial vacuum as applied in the manufacture of paper.* (A communication.) Dated November 24, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3151. R. and W. Hawthorn. *Improvements in pump valves.* Dated November 24, 1862.

This invention consists in the application of an annular double mitre valve to pumps of every description, but specially adapted for the air-pumps of surface-condensing engines, or where a free passage with a small rise or lift, and where a quick action is desirable, as in the case of pumps worked at higher speeds; and further, in the the application of a peculiar ball, clack, or valve, or any number of them, for the same purposes. The double beat or mitre valve first named contains an annular space or ring between the inner diameter of the outer mitre, and the outer diameter of the inner mitre, of sufficient area to allow the water or other liquid a passage proportioned to the requirements of the pump. The upper portion or lid of the valve is formed of cast iron and wood, the wood part forming the mitres corresponding with those formed in the annular space in the valve seat. The lid of the valve is guided by a centre bolt of copper, or other material, with a collar or stop on the top end of it, by which the lift of the valve is regulated. The ball, clack, or valve consists of a circular seat of hard wood, fitted into a plate forming the bottom of the valve box, upon which a ball falls and closes the passage at each stroke of the pump. The balls may be made of cast iron or other material, either hollow or solid, and the lift regulated by suitable provision. *Patent completed.*

3152. J. Barclay. *Improvements in the construction and arrangement of rollers to be used in machinery for printing textile materials and fabrics, and in apparatus for drying and finishing the said materials or fabrics.* Dated November 24, 1862.

The first part of these improvements has reference to the construction of rollers to be used in the said printing machinery. These rollers are formed by preference of cast iron, or other suitable rigid non-yielding material. The periphery of each roller has formed in it a series of grooves of a dovetail figure, the greatest width being at the lower part of the groove. In these grooves are fitted lengths of wood, or the grooves may be filled with lead, or a metallic alloy, or with gutta percha, or other material suitable for affixing thereto the printing surfaces. In lieu of these grooves, the rollers may be made with slots or other apertures, so as to admit of slips of wood, or other suitable material, or of the engraved surfaces being affixed thereto in any convenient manner. These rollers are arranged to work in colour troughs, and to convey the colour on to the yarn or fabric passing round the printing cylinder. This portion of the machiney forms, however, no part of the present invention. The rollers are arranged in a segmental figure, extending round a portion of the periphery of the printing cylinder, and on the other side of the cylinder is fitted a roller covered with flannel, or other suitable material, which serves to brush the surface of the cylinder, and remove therefrom any colour which may adhere to it. This brushing roller is fitted below the surface of the cloth or yarn which is passing off from the upper part of the cylinder. If required, the roller may be caused to rotate in a trough of water, in order to cleanse more effectually the surface of the cylinder. In some cases, another and corresponding roller and trough may be fitted below, so that the cylinder is submitted to a second cleansing process before the imprinted yarn or cloth passes on to it, and each roller is fitted with a "doctor", or scraper to remove the moisture which the roller carries on to the cylinder. As the yarn or cloth is carried off from the cylinder, it passes through a drying apparatus, which constitutes the second part of this invention. This drying apparatus consists of a series of rollers arranged in pairs one above another. The yarn is carried up and down over and beneath these rollers, so as to present an extended surface to the action of the heat. *Patent abandoned.*

3153. J. H. Johnson. *Improvements in burnishing metal* *surfaces, and in the machinery or apparatus employed therein.* (A communication.) Dated November 24, 1862.

This invention relates to a mechanical and automatic burnishing of metal surfaces of all kinds, in lieu of the ordinary hand process hitherto adopted, and to a peculiar construction and arrangement of machinery or apparatus to be employed in burnishing metal surfaces. According to this invention, one or more articles to be burnished are properly adjusted upon suitable holders placed on a table, which is capable of lateral and transverse horizontal adjustment, by means of screws, racks, or otherwise. Immediately above the articles to be operated upon are arranged one or more series of burnishing tools, fitted with corresponding vertical spindles, which are capable of rotating individually by means of pulleys or otherwise, in a suitable frame contained in vertical guides at each end, so as to admit of the burnishers rising and falling and being lifted off or lowered down upon the articles to be burnished. In this frame there is also fitted a tracer point, which travels over a pattern surface corresponding exactly in size and shape with the articles to be operated upon. Each burnisher is pressed down by a helical or other spring upon the corresponding article beneath it. On imparting a rapid rotary motion to the several burnishers, and slowly traversing the tables containing the articles and the pattern surface to and fro in both directions, either simultaneously or separately, the burnishers may be made to work over the entire surface of such articles, and will rise and fall to accommodate themselves to any irregularity in the surface by the action of the tracer upon its pattern. *Patent abandoned.*

3154. E. Leigh. *Improvements in cotton gins.* Dated November 24, 1862.

In that kind of cotton gin called the "Macarthy" gin, the inventor places two, four, or more rollers, instead of one, as heretofore employed. These rollers, acting in pairs, are placed in a horizontal line about 14 in. apart in a frame, the length of which is determined by a number of rollers or power of gin required. In order to get the seed cotton delivered regularly to each pair of rollers, he places a hopper between them. The bottom of this hopper which receives the seed cotton is placed about 8 in. or 10 in. above the gin rollers, and is furnished with a pair of ragged feed rollers, which draw down the seed cotton and deliver it to be ginned, forming a vertical or drop feed, which can be regulated at pleasure. Instead of a single oscillating doctor, he makes one with double arms, having a blade at each end. These arms and blades, forming a compound lever, balance each other, and are actuated by one crank or eccentric motion; so that, when one knife is up, the other is down acting upon each gin roller alternately. These gin rollers are covered with leather having spiral grooves in the ordinary manner, excepting that he makes them of iron, which he covers with woollen cloth, india rubber, or other elastic substance under the leather. *Patent abandoned.*

3155. W. Tatham. *Improvements in machinery or apparatus for preparing and spinning cotton, wool, flax, and other fibrous materials.* Dated November 24, 1862.

In the machines known as openers and scutchers, the patentee applies a bar with a concave under surface to the top of the feed roller, between which and the bar the fibrous materials pass. The edge of the bar near the toothed cylinders or beaters, is nearly level with the centre of the feed roller, so as to hold the fibrous material more firmly between the bar and the feed roller than with the ordinary upper roller, and thereby enable the material to be more effectually operated upon than with two feed rollers. 2, In carding engines he applies a concave bar above the feed roller, similar to that before described for the opener and scutcher, and also makes the contact surface of the taker-in or cylinder and feed roller revolve in one and the same direction, in order to strip the fibrous material from the feed roller and concave bar in the same direction as that in which the feed roller revolves, which system of causing the taker-in or feed roller to revolve in the same direction, he applies to those carding engines in which the bar or plate is beneath the feed roller. 3, In doubling, drawing, or slubbing and roving frames, or in throstles, mules, and other spinning machines where drawing rollers are generally used for restraining and drawing or elongating the fibres of cotton or other fibrous material, he applies the following improvements—one part of which consists in drawing the fibrous material in each machine between two pairs of rollers only, which, when properly adjusted, are quite sufficient for restraining, drawing, or elongating the fibrous materials without the assistance of the usual additional drawing rollers; and the other part consists in employing an additional roller in connection with the aforesaid two pairs of drawing rollers, or using three rollers and bar. *Patent completed.*

3156. N. J. Amies. *An improved fabric to be employed as a substitute for elastic woven or braided webs, and improvements in the method of manufacturing the same.* Dated November 24, 1862.

This improvement consists in cementing or otherwise attaching a covering or coating of piece silk, or other woven fabric, to a surface, layer, or foundation of india rubber, or, if preferred, on each side of the india rubber, and so forming an economical substitute for the expensive elastic webbing at present employed. *Patent abandoned.*

3157. J. Moule. *An improved method of deodorizing mineral oils and hydro-carbons.* Dated November 25, 1862.

This invention consists in using deutoxide of azote or nitrous gas in any form, or nitrous acid may be used, for the purpose of deodorizing and destroying the peculiar and disagreeable odour found in various samples of petroleum and other rock oils, including paraffin oil, and also for removing and changing the odour of other liquids, the products of petroleum, coal, and other substances. *Patent completed.*

3158. T. and L. Robertshaw. *Improvements in the manufacture of textile fabrics, technically called "moreens."* Dated November 25, 1862.

This invention consists in the substitution of jute or hemp for worsted to form the weft in the manufacture of the fabrics technically called "moreens," that is to say, whereas hitherto fabrics known by this name have been manufactured with a worsted warp and worsted weft, under this invention they will be manufactured with a worsted warp and a weft composed either of jute or hemp. The mode of manufacturing such fabrics is in other respects the same as that now in use. *Patent abandoned.*

3159. A. L. Woolf. *A new or improved metallic alloy.* Dated November 25, 1862.

This invention consists of a new or improved metallic alloy, which is highly malleable and ductile, and of a colour scarcely to be distinguished from that of gold. The said alloy is less liable to oxidize or tarnish than other base metals or alloys, and is suited for the manufacture of jewellery; it may also be applied to other purposes. The said alloy is composed of from 90 to 100 parts weight of copper, from 5 to 7½ parts by weight of aluminium, and 2½ parts by weight of gold. In making the said alloy, it is only necessary to melt together in a crucible the respective quantities of the several metals of which it is composed, when on fusion the metals immediately enter into alloy. *Patent completed.*

3160. E. Wadsworth. *Improvements in machinery used in the manufacture of certain descriptions of braid.* Dated November 25, 1862.

This improvement in braiding machinery is applicable to those machines in which gut, india rubber, or other thick threads are interwoven with or covered by the braiding thread, and consists in effecting the stoppage of the braiding machinery by so arranging or connecting a lever or weight with thick or foundation threads that, in the event of their becoming detached or broken, or not forming one contiuous thread from the supply spools or bobbins to the manufactured braid, the said lever or weight shall come into contact with any suitable arrangement of mechanism, as may be designed, to stop the machinery, thus making the disunion of the thread stop the machine by self-acting means. *Patent completed.*

3161. J. S. Jarvis and J. H. Brierley. *Ladies and gentlemen's leather collars.* Dated November 25, 1862.

In carrying out this invention, the inventors make use of and cut or form white or coloured enamelled or any other kind of leather into such shape or configuration as to be suitable for ladies or gentlemen's collars of any kind or description. That portion overlaying the ladies' dress, and that portion overlaying the gentlemen's tie, is single or unlined leather, and ornamented as required. The inner or other part of ladies or gentlemen's collars is double or lined leather, with calico inserted between the two leathers at the points where the button-holes are cut, if the leather be of such a nature as to require the same. *Patent abandoned*

3162. W. B. Caulfield. *Porous stems for tobacco pipes.* Dated November 25, 1862.

According to this invention, a tube of any convenient diameter is composed of the pulp of rags, or any other fibrous material, or from felt, or from paper rolled up together, more particularly of such paper as is commonly known as "blotting paper." This tube is to be used inside of the stem of a tobacco pipe, or as a stem by itself; it will absorb the essential oil and juices arising from the combustion of the tobacco, and will prevent the smoker from suffering any hurt or inconvenience therefrom, until it becomes saturated, when it can be instantly replaced by another fresh and clear stem. *Patent abandoned.*

3163. G. Henderson. *Improvements in steam-engines.* (A communication.) Dated November 25, 1862.

This invention consists in a peculiar combination of parts, by which some of the steam generated may be used in two or more cylinders in succession, without that back pressure on the piston in the first cylinder which has heretofore resulted when using steam expansively in two or more steam cylinders. The combination is such, that each of the steam cylinders is capable of being put in communication with a condenser, or with the outer atmosphere on one side of the piston when steam is being admitted into the cylinder on the other side of the piston. To accomplish this, the steam is expanded from the first steam cylinder into a vessel which the patentee calls an "accumulator," from which the steam is supplied to another steam cylinder, the communication between the first steam cylinder and the accumulator being closed by a suitable valve when steam from the accumulator is being supplied to another steam cylinder. The working of the machinery is such, that on opening the exhaust from the first steam cylinder, the steam expands into the accumulator of an additional steam cylinder, and then to the condenser, if only one additional cylinder be employed; but if more than one additional steam cylinder be used, then the exhaust, having been opened to the first accumulator, is cut off therefrom, and the exhaust steam is then allowed to expand into the accumulator of a second additional steam cylinder before the exhaust of the first cylinder is allowed to pass to the condenser. It is preferred to employ two accumulators and two additional steam cylinders. *Patent completed.*

3164. G. Ransome. *Improvements in apparatus for preparing clay for brick-making and other purposes.* Dated November 25, 1862.

This invention consists in the following improved sieves, and the mode of agitating them:—The patentee takes an ordinary sieve of the rectangular form, about 4 ft. 6 in., or 5 ft. in length, and about 2 ft. 6 in. in width, and suspends it horizontally in a suitable framework by four leather straps, one at each corner, from beams above it, one end, however, being about 3 in. higher than the other. He then fixes into the bottom of it, about 6 in. apart, several slack thin iron chains of ⅛-in. iron, the ends of which are fastened to the opposite ends of the longer length of the sieve. These chains are to be about 2 in. in length longer than the sieve, so that, when the sieve is in motion, the slack parts shake about among the clay under operation without coming in actual contact with each other. To the sieve so suspended and constructed he attaches a crank shaft, descending perpendicularly upon it from above, the crank being at the lower end, and fitted with a socket inserted into a cross bar extending from side to side over the centre of, and firmly secured to, the sieve. He uses a crank, the arm of which, when in motion, describes a circle of 8 in. in diameter. The shaft is made to revolve by any of the ordinary methods in general use, and when in motion, and charged either by hand or from a shoot above, the sieve is agitated in a circular horizontal manner, whereby the clay is sifted or screened, the fine being collected for use, and the rough, or lumpy parts, passing away as in ordinary methods. *Patent completed.*

3165. A. V. Newton. *Improvements in sewing machines.* (A communication.) Dated November 25, 1862.

This invention relates more especially to those machines which are employed in uniting or stitching together the edges of a fabric, and has for its object the production of a machine which shall be capable of working a button-hole or other similar article in a practically successful manner by automatic means. The extreme length of the specification precludes a detailed description of the invention here. *Patent completed.*

3166. W. Longley. *Improvements in machinery for making bricks.* Dated November 25, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3167. T. M. Elton. *Improvements in the manufacture of soap and in the machinery employed therein.* Dated November 25, 1862.

This invention consists of an improved manufacture of that class of soap known as mottled or marbled and fancy soap, and also in the machinery whereby such improved soaps are made. The patentee constructs the machinery as follows:—He forms a frame of an oblong or square form, supported on wheels or otherwise, at one end of which a hopper is fixed at the top of the frame; the exit passage at the bottom of the hopper is regulated by means of a vertical slide the entire width of the passage, below which a drum or cylinder is fixed on a shaft and set in bearings in the frame. This drum extends across the machine, and is of the full internal width of the frame, and another similar drum is placed at the other end of the frame. These drums are enclosed by an endless band or belt of leather, felt, or printer's flannel, or other suitable material (the patentee finds in practice that canvas coated with india rubber is very well adapted to the purpose), the surface of which should lie in an oblique direction by the requisite position of the machine. This endless band is supported between the drums by means of a flat board or metal plate, so as to preserve a perfect level, and the drum at the end of the machine furthest from the hopper is set in moveable bearings or blocks, so as to enable the band to be always kept tight thereon: the bottom of the hopper reaches the surface of the band. At the end of the machine last referred to, and beyond the drum, a vessel is placed which contains a coloured soap or a colouring liquid or pigment in solution. This soap or liquid is kept in a heated state by means of a small furnace. Above this vessel a cylindrical drum is set in bearings in the frame. Attached by hinges to this drum is a series of bars of metal, running lengthwise of the drum at regulated distances apart; these bars carry rows of metal scrapers having their ends turned up at an angle, so as to form flat-headed scoops, and these scoops or scrapers pass through the coloured soap or liquid, and carry it round with them. This drum receives the rotary motion, by means of a band and grooved pulley, from the first drum which works the endless band. The driving wheel actuates a cogged wheel gearing into another toothed wheel on the shaft of the first drum, whereby motion is communicated to the machine. *Patent completed.*

3168. T. Fletcher. *Improvements in the construction of rollers, cans, spools, and bobbins, and in the machinery employed therein.* Dated November 26, 1862.

This invention is not described apart from the drawings. *Patent completed.*

3169. J. Aspell and E. Booth. *Certain improvements in looms for weaving.* Dated November 26, 1862.

This invention relates to that portion of the power loom known as the letting off motion, and is designed for the purpose of regulating the tension and the "letting off" or delivery of the yarn. The improvement consists in applying or employing the movement or vibration of the woven cloth (caused by the "shedding" and "beating up" motion) to the letting off or delivery of the warp, by any mechanical arrangement interposed between the woven cloth and the warp beam. *Patent abandoned.*

3170. J. Steinthal. *An improved moulder's blacking.* Dated November 26, 1862.

Instead of the ground charcoal hitherto used by moulders in the process of making metal castings, the patentee uses the following materials in about the following proportions:—Wood charcoal, 0·45; anthracite, commonly called shale or slate, 0·45; animal carbon, 0·10; with a small quantity of prussiate of potash. The said materials are to be well mixed together and reduced to a fine powder by grinding, pounding, or other suitable means. He subjects the anthracite used in the manufacture of this improved blacking to the process of cokeing in a stove or kiln, by which the paraffin, oily, and sulphurous substances and gases are extracted. The anthracite and animal carbon being non-conductors, withstand the sulphuric gases of the fluid metal, so that the coat of blacking between the mould and the metal remains intact, the fluid metal forming a perfect casting, thus preventing blisters and blemishes on the castings caused by the affinity of the the sulphuric gases to the silicate contained in the sand. *Patent completed.*

3171. F. Palling. *An improved fountain penholder.* Dated November 26, 1862.

This invention consists in so constructing a fountain penholder that, when a writing nib or pen is adapted thereto, the said nib, when pressed upon the surface of the material to be written upon, shall cause pressure upon an elastic tube containing the writing fluid, and cause the said fluid to be discharged therefrom intermittently. *Patent completed.*

3172. J. F. Foveaux. *Improvements in apparatus for pulverizing or dividing liquids into spray.* (A communication.) Dated November 26, 1862.

This apparatus consist of a syringe barrel with a contracted outlet leading into, by preference, a flexible metal tube (but any other tube may be used), on the outer end of which a nozzle is screwed or otherwise fitted. The aperture in the nozzle is more or less contracted according to the distance to which the spray is to be projected, and to the degree of fineness required. Inside the syringe barrel a piston is fitted and is worked by a screw piston rod passing through a threaded nut in the cover of the barrel. The apparatus is applicable to medical, horticultural, and other purposes where liquid in minute spray or in a state of dew is desired. *Patent completed.*

3173. W. Austin. *An improved material for the manufacture of cartridge cases, applicable also for tubing and other useful purposes.* Dated November 26, 1862.

This material is to be made as follows:—The inventor proposes to take a woven fabric of cotton or flax, or other fibrous substance, and coat the same with any suitable adhesive solution, after which it is to be covered with a layer of paper on one or both sides, and then subjected to pressure, either by rolling flat, or other pressure hot or cold. *Patent abandoned.*

3174. J. R. Danks, and P. B. and R. P. Walker. *Improvements in machinery or apparatus for making boot and shoe heel and toe tips, clog irons, and other similar articles.* Dated November 26, 1862.

This invention consists in constructing machines for the manufacture of boot and shoe tips, clog irons, and other similar articles, in such a manner that the operations of bending the pieces of metal intended to be formed into tips or other articles, and afterwards piercing the tips or other articles with the necessary holes for the reception of the fastenings, are performed automatically in one machine, in place of each operation being performed separately as at present. *Patent completed.*

3175. A. V. Newton. *An improved mode of preparing oxide of zinc as a pigment.* (A communication.) Dated November 26, 1862.

The object of this invention is to enable the white oxide of zinc to be manufactured into paint having a desirable degree of body, and to this end the invention consists in subjecting it in its dry state to the combined action of friction and pressure, by which means its bulk is greatly reduced, and it is enabled to be ground with a reduced quantity of oil. *Patent completed.*

3176. J. Halford. *Improvements in the preparation and treatment of a mineral substance to be used in, and in the manufacture of, iron and steel in the processes of casting and moulding metals, and in the manufacture of paint and such like articles.* Dated November 27, 1862.

We cannot here devote space to the details of this invention. *Patent completed.*

3177. A. A. Pheloux and P. A. Paumier. *A new atmospheric sailing propeller.* Dated November 27, 1862.

This new atmospheric sailing propeller is composed of a reservoir with double casing, into which reservoir air is introduced by means of suction and force pumps worked by steam. The air being brought into the reservoir is compressed several atmospheres, according to requirement, and escapes by blow-pipes placed tangentially to the side of the ship, at an inclination varying with the draught thereof and the speed required. There are two blow-pipes on each side of the ship turned towards the prow, and two towards the poop. The impulsion is given by the air, which, escaping from the reservoir by the blow-pipes, comes forcibly against the mass of water. Two blow-pipes, uniting into one near the reservoir, are placed on each side the rudder beneath the water-line, and may, in case of accident to the wheel or tiller, serve conjointly with the side pipes to work the ship, obviating the necessity of replacing the rudder, which might, in fact, be entirely superseded by this system. The waste steam circulates within the double casing of the reservoir, and heating the air gives it a greater expansive power. *Patent abandoned.*

3178. F. W. Hartley. *Improved means of obtaining certain products resulting from the manufacture and purification of coal gas.* (A communication.) Dated November 27, 1862.

This invention has for its object the adoption and emploment of certain improved means (which we cannot here describe in detail) for obtaining sulphate of ammonia from the oxide of iron used in purifying gas, by which a larger quantity of sulphate of ammonia is produced and the cost of such production is lessened. *Patent abandoned.*

3179. T. Keyworth. *Improvements in motive power machinery.* Dated November 27, 1862.

This invention consists of a series of jointed levers, all of the same length, excepting the last lever, which may be either longer or shorter than the other levers, and may be either jointed or not. The fulcrum of each jointed lever aforesaid should be so placed as to give a lever power of three to one. These levers the patentee proposes to arrange and dispose side by side, as follows:—He places the second lever with its short arm opposite to the long arm of the first lever, and the third lever he arranges the same as the first lever, and in this manner he arranges the several levers with respect to each other. In connection with the long arm of each jointed lever aforesaid, he employs a jointed metal belt, passing around two rollers placed one above the other, and to this belt he connects the long arm of the jointed lever aforesaid. The rollers aforesaid are each mounted on one end of a spindle working in suitable bearings, and on the other end of the said spindle a pinion is fixed, the said pinion taking into the teeth of a sun-and-planet wheel, the axis whereof is midway between the axes of the two rollers aforesaid. The outer rim of the aforesaid sun-and-planet wheel has bevelled teeth formed thereon, which gear into a bevelled pinion fixed on a crank spindle revolving crosswise of the axis of the aforesaid sun-and-planet wheel. The two cranks of the aforesaid cranked spindle are formed at right angles, or nearly so, to each other, and are connected each by a horizontal rod to two other similar cranks on a spindle placed parallel to the first-named cranked spindle, the use of the said rods being to pass the mill-point of said cranks. When more than one jointed lever aforesaid is employed, the patentee employs a sun-and-planet wheel and jointed belt before described to each and every jointed lever employed for imparting motion thereto. The short end of each jointed lever is connected by a vertical rod to another cranked spindle or shaft for imparting rotary motion thereto. He also proposes to affix a fly-wheel on the end of the said spindle or shaft. The motive power obtained by the above improved machinery may be transmitted in any convenient manner, according to the purpose for which it is required. *Patent completed.*

3180. W. T. Rowlett. *Improvements in machinery used in producing knit or looped fabrics.* Dated November 27, 1862.

For the purposes of this invention, it is preferred that a series of independent sinkers should be employed, suspended on a wire or axis at their upper ends. These sinkers are kept correctly in position by working between the teeth of a comb. The row of needles is mounted or fixed on a bar which receives a rising and falling motion, the needles being fixed in an upright position, but the needle bar or the needle thereon may be arranged to turn down into a horizontal position in order to place work on the needles. The sinkers are constantly pressed back in a direction from the needles by springs. The needles work between teeth on a stationary bar, which acts as a knocking-over bar to knock over the work as the needle bar descends; but, if preferred, the needle bar may be stationary and the knocking-over bar be made to rise and fall. In order to actuate the sinkers in succession, a barrel or cylinder is used, on which is formed a cam or inclined or spiral projection, which, acting on the backs of the sinkers, presses them forward in succession, so as to sink the thread or yarn between the needles and retain the sinkers in that position for a time. On the axis of the barrel or cylinder are cams to act on suitable levers or intervening instruments to cause the needle bar to rise and fall, or, in place thereof, the knocking-over bar. The thread carrier is of the ordinary construction, and is caused to move to and fro across the row of needles by cams on the axis of the barrel, or otherwise. In working a course with this machine, the thread carrier lays a thread across the needles, and the sinkers, by the action of the spiral or cam surface thereon, acting on the backs of the sinkers, are caused in succession to sink the thread between the needles, which are preferred to have beards or tongues which move on axes. The descent of the needle bar will then cause the needles to descend, whilst the work is supported by the knocking-over bar, and beyond the open moveable beards of the needles, by which the work, acting on the beards, will cause such beards to shut and inclose the new loops within the eyes of the needles, and the further descent of the needle bar will cause the work to be knocked over, or the working of the sinkers employed may be so arranged as themselves to knock over the work. The needle bar will then be caused to rise to its highest position, when the thread carrier will be again moved across the row of needles, and will lay its thread across them, whilst the spiral cam or surface of the barrel or cylinder will cause the sinkers to sink the thread between the needles, and so on continually. In order to vary the length of loops, the bearings of the axis of the barrel or cylinder are arranged to admit of being adjusted in a direction to or from the front of the machine; or in place thereof, the needle bar may be arranged to be adjusted to or from the barrel or cylinder. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated March 11, 1863.

669. A. Barclay, Kilmarnock, engineer. Improvements in traction engines and in apparatus for indicating the pressure of steam.

Dated April 21, 1863.

997. W. Ryan, 17, Fishamble-street, Dublin, engineer and machinist, and W. Daniel, 55, Mary-street, ironmonger and gas engineer. Improvements in apparatus for transmitting, equalizing, and registering human power.

Dated April 28, 1863.

1062. G. Hall and J. Wells, Worcester. A new explosive compound, applicable for all the purposes for which gunpowder is or may be used.

Dated May 8, 1863.

1157. E. C. Boët, Lille, France. Improvements in tanning hides and skins. (A communication.)

Dated May 11, 1863.

1180. C. L. V. Tenac, Tredegar, Monmouthshire, civil engineer. A new wrought-iron railway sleeper. (A communication.)

1181. C. L. V. Tenac, Tredegar, Monmouthshire, civil engineer. Armour plates of hammered or rolled wrought iron, the whole of the rivets being protected against the direct blows from the cannon shots.

Dated May 21, 1862.

1273. F. P. Warren, East Court, Cosham, Commander in the Royal Navy. Improvements in attaching copper or other sheathing to iron vessels.

1281. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in breech-loading ordnance, breech-loading and other small arms. (A communication.)

Dated May 23, 1863.

1292. J. Sturgeon, Leeds, York, consulting engineer. Improvements in steam hammers.

Dated May 25, 1863.

1318. M. J. Roberts, Pendarren, near Crickhowell, esquire. Improvements in means of, and apparatus for, preparing, spinning, twisting, and doubling wool, cotton, and other fibrous substances, and in lubricating the spindles and other parts of machinery used in these and other operations.

1319. J. W. Burton, S. G. Rhodes, S. F. Seanor, Leeds, and W. Scruton, Liverpool. An improved machine or apparatus for getting coal or other minerals.

Dated June 1, 1863.

1364. J. Chalmers, 8, Knight's-place, Vauxhall. Improvements in armour for forts and floating batteries.

1366. F. W. Smith, 180, Upper Thames-street, merchant. Improved apparatus for conveying of goods either in bulk or otherwise, whether to or from the warehouse or vessel having an inclined vertical or horizontal movement, to be worked either by pressure of air or by vacuum and atmospheric pressure.

Dated June 2, 1863.

1380. E. H. Létang, 12, Rue du Chemin de Reuilly, Paris. An improved ruling and printing machine to be used either combined or separately.

Dated June 3, 1863.

1384. J. Travis, Luzley Brook, Lancaster, gentleman. An improved method of preventing the incrustation of earthy matter in steam boilers, steam generators, and fuel economizers.

1388. W. Lee, 23, Sumner-place, Onslow-square, and J. G. Winter, 73, Great Suffolk-street. Improvements in steam fire-engines. (A communication.)

Dated June 5, 1863.

1400. R. W. Sievier, Guildford-street, Russell-square. Improvements in jacquard machines. (A communication.)

1402. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in treating liquorice root to obtain liquid and solid extracts therefrom. (A communication.)

1406. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in smoothing irons. (A communication.)

Dated June 8, 1863.

1412. N. Walton, Aldenham-street, Saint Pancras. Improvements in apparatus for drying and airing clothes.

1416. W. Clark, 53, Chancery-lane, engineer. A new and useful device for turning cross head wrists or pins, or for turning any cylindrical part of machinery which is secured between two arms. (A communication.)

1420. J. G. Jones, Cumming-street, Pentonville, and R. Ridley, Leeds. Improvements in machinery and apparatus for working coal and other mines.

1422. R. C. Furley, Edinburgh. Improvements in the preparation of castor and other oils for medicinal use.

1424. W. E. Newton, 66, Chancery-lane, civil engineer. An improvement in needles. (A communication.)

1426. J. Petrie, Rochdale, machine maker. Improvements in machinery or apparatus for washing wool and other fibrous materials.

Dated June 9, 1863.

1428. G. Hills, Blackheath, chemist. Improvements in obtaining certain products from hops.

1430. E. Barlow, Bolton, machine maker, J. Newhouse, Farnworth, near Bolton, manager, F. Hamilton, foreman, and W. Hope, carder, Bolton. Certain improvements in machinery for grinding card teeth.

1432. J. Edwards, 29, Basinghall-street. Improvements in railway chairs and sleepers.

1434. J. Murray, Whitehall-place, solicitor. Improvements in clips or holders for inserting and fixing photographic pictures in albums.

1436. M. Siegrist, Ewell. Improvements in the construction of fountains.

1438. H. F. McKillop, captain Royal Navy, Belvedere. Improvements in compositions for coating or covering ships bottoms.

Dated June 10, 1863.

1440. W. Madders, Manchester, embroiderer by machinery. A new and improved ornamental fabric.

1442. W. Roberts, Millwall, Poplar, engineer. Improvements in steam boilers.

1446. T. Evans, Manchester, and E. Hughes, letter press printers. Improvements in apparatus for applying one or more colours of ink to type in letter press printing by hand.

Dated June 11, 1863.

1450. T. M. Harrison, Birmingham, manufacturer. An improvement or improvements in the manufacture of metallic casks.

1452. J. F. Kain, Fleur-de-lis-street, Norton Folgate, ivory worker. Improvements in umbrellas, parasols, sunshades, walking sticks and whips, and in brooches and othe ornaments.

1456. J. Webster, Birmingham, engineer. Improvements n indurating iron, and in protecting iron and steel from oxidation.

1460. E. O. Hallett, Weymouth and Melcombe Regis, Dorset, cabinet maker. Improvements in constructing the sides of ships, batteries, and fortifications, and in applying armour plates thereto.

1462. J. Johnson, Peterborough, engineer, and W. Braithwaite, foreman. Improvements in reversing levers for locomotive engines and others.

LIST OF SEALED PATENTS.

Sealed June 19, 1863.

3417. R. A. Brooman.
3437. G. Haseltine.
3435. A. P. Tronchon.
3138. W. Henderson.
3444. J. Taylor.
3445. J. and W. Lord.
3454. E. T. Loseby.
3470. J. Johnston.
20. J. E. Dowson.
276. F. G. Stuber.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, June 23, 1863.

358. J. Goucher. Regulating the admission of air into the furnaces of steam boilers.

362. T. Hill. Protection of markers at rifle butts.

365. M. Cartwright. Combining plastic substances with metals.

369. H. Donald. Machinery for shearing, punching, and riveting metals.

381. A. Morton. Lawn mowing machines.

385. G. H. Birkbeck. Separating or extracting silver or other metals from lead. (A communication.)

386. S. M. C. Innes. Pianofortes.

388. J. Jones. Manufacture of lead, tin, and other metals.

393. G. Wrigley and S. Morris. Spinning and doubling.

396. S. Whitaker. Railway signals.

401. J. S. Gisborne and W. Simpson. Rendering ships' and other compasses insensible to local attraction.

402. H. Dembinski. Motive apparatus and processes proper for giving to it a continuous motion and unlimited strength.

410. J. and H. Higgins. Carding engines.

413. J. H. Johnson. Wrought-iron casements. (A communication.)

418. J. B. Watts. Matchets and swords.

420. R. A. Brooman. Cover or protection for steel and other metal springs, ribbons, and hoops. (A communication.)

432. J. Durrant. Chimney tops.

452. T. Markland and J. C. Dickinson. Warping or beaming yarns or threads.

459. H. B. Barlow. Weaving. (A communication.)

462. C. Billingsley. Saddlery, harness, driving straps, and similar articles.

473. H. Kilshaw and T. Elce. Preparing and doubling fibrous substances.

481. J. Brown. Armour plates for ships and other structures. (A communication.)

491. R. Martindale. Lamps and burners.

498. W. Whitehead, H. Whitehead, and H. Barber. Manufacture and securing of cutlery, handles, and machinery employed therein.

499. J. Clay. Manufacture of saddles.

544. W. Clark. Manufacture of buttons. (A communication.)

564. W. Hadfield. Steam-boilers.

586. W. Clark. Photographic impressions. (A communication.)

646. R. Mushet. Manufacture or treatment of pig or cast iron.

656. J. R. Gorst. Carriages.

665. W. R. Mulley. Sheathing iron ships, caissons, and other like structures.

691. W. West. Valves.

714. W. H. Emett. Facilitating and combining the art of writing with engraving together on stone, applicable to maps, plans, specifications, and other lithography, which improvements are also available for retransfers to zinc or stone or printing from original.

749. G. Coles, J. A. Jaques, and J. A. Fanshawe. Washing and wringing clothes or fabrics.

788. R. Mushet. Pneumatic process.

818. R. Mushet. Improvements in moulds.

848. D. S. Sutherland. Protecting vessels of war.

1080. W. Rodger. Anchors.

1252. F. Fenton. Treatment of certain vegetable fibres.

1264. P. Addington. Manufacture of varnishes.

1309. H. A. Bonneville. Construction of carriages. (A communication.)

1402. R. A. Brooman. Treating liquorice root to obtain liquid and solid extracts therefrom. (A communication.)

The full titles of the patents in the above lists can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

Sealed June 23, 1863.

Abridged Specifications of Patents	450
Provisional Protections	453

The *Standard*, November 15, speaking of Benson's watches in the Exhibition, says:—"It has evidently been Mr. Benson's object to render them rivals in point of beauty of decoration to the elegant Swiss knicknacks, and at the same time to preserve the characteristics of an English watch—strength, durability, and accuracy. In point of decoration his watches are certainly unsurpassed." Chronometer, duplex, lever, horizontal, repeaters, centre seconds, keyless, split seconds, and every description of watch, adapted to all climates. Benson's Illustrated Pamphlet on Watches (free by post for two stamps) contains a short history of clock and watch making, with descriptions and prices; it acts as a guide in the purchase of a watch, and enables those who live in Scotland, Ireland, Wales, the Colonies, India, or any part of the world, to select a watch, and have it sent free and safe by post.—J. W. Benson, Prize Medallist, 33 and 34, Ludgate-hill, London. Established 1749.
